

OPAC-1 International Workshop

Graz, Austria, September 16 – 20, 2002

Advancement of GNSS Radio Occultation Retrieval in the Upper Stratosphere

A. Gobiet and G. Kirchengast

Institute for Geophysics, Astrophysics, and Meteorology (IGAM),
University of Graz, Austria

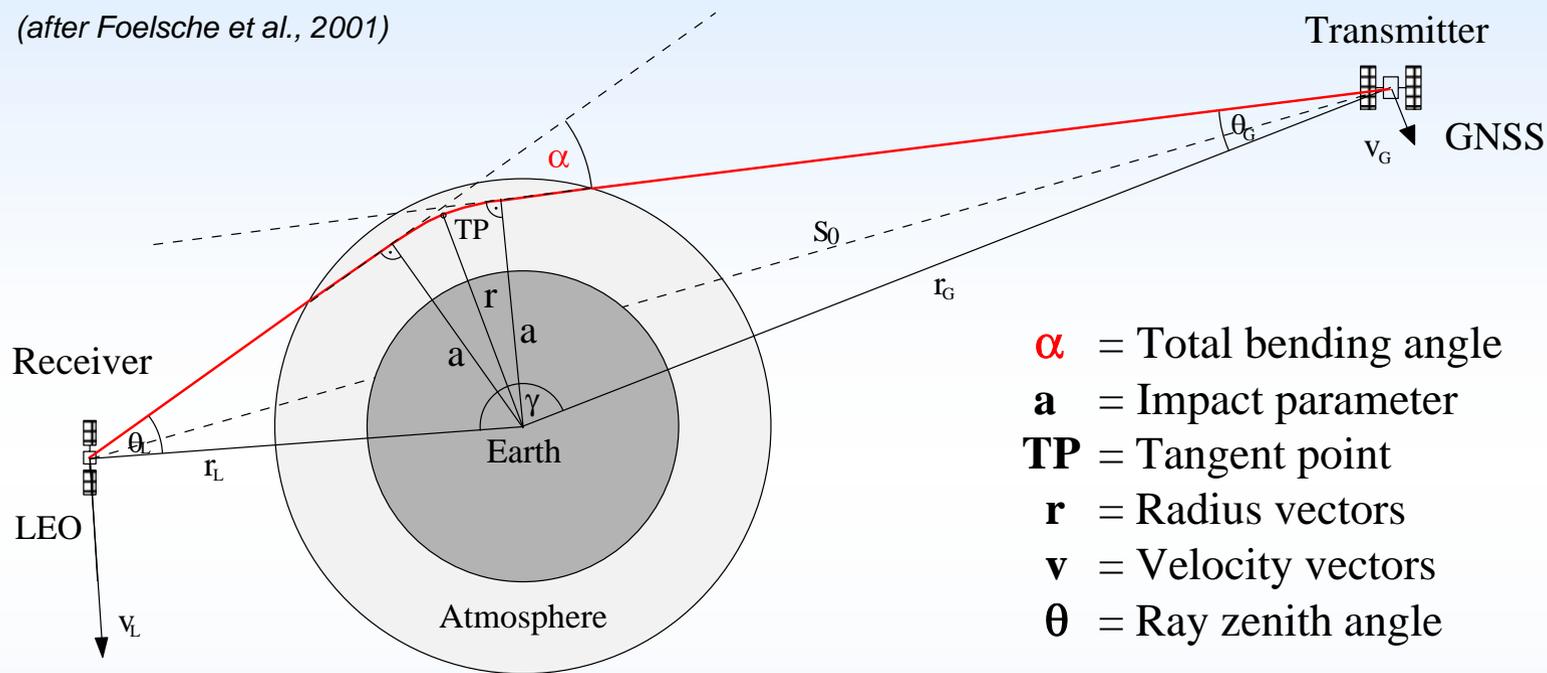

Outline

- **Radio Occultation (RO) – overview**
- **RO-based climatologies**
- **Stratospheric RO retrieval**
- **Stratospheric retrieval validation study**
- **Advancing upper stratospheric retrieval / background bias correction**
- **Results**
- **Summary, conclusions, and outlook**

Radio Occultation Overview

(after Foelsche et al., 2001)

- α = Total bending angle
- a = Impact parameter
- TP** = Tangent point
- r = Radius vectors
- v = Velocity vectors
- θ = Ray zenith angle

- **Transmitter:** Global Navigation Satellite System (GNSS); GPS, GLONASS, GALILEO
- **Signal:** L – Band (GPS: L1, $f_1=1575.4$ MHz; L2, $f_2=1227.6$ MHz)
- **Receiver** on Low Earth Orbit (LEO)
- **Primary observable:** Phase delay L

$$L = \int_{GNSS}^{LEO} n \, ds - S_0$$

Utility for Climate Monitoring

- **Global coverage**
 - Equal observation density above oceans and land
 - Equal observation density in northern and southern hemisphere
- **All weather capability**
 - Virtual insensitive to clouds and aerosols due to long wavelengths
- **High accuracy and vertical resolution**
 - Temperature error < 1 K at ~ 1 km resolution
- **Long-term stability (intrinsic self-calibration)**
 - Expected temperature drift < 0.1 K/decade

Realization of RO Climatologies

First opportunity for real RO climatology: **CHAMP (and SAC-C)**

- Continuously >150 occultation events per day
- First retrieval results encouraging (error <1 K in ~12 – 25 km interval), but bias above ~25 km
- Sampling error allows large-scale climatologies (>1000 km horizontal scale)
- Data may be complemented by SAC-C and GRACE in near future
→ up to 1000 occultation events per day
- Further future perspectives: METOP/GRAS, COSMIC, ACE+, . . .

Realization of **CHAMPCLIM**

- Background-independent via statistical interpolation and averaging
- Weakly background-dependent but higher resolved via data assimilation
 - 3DVAR assimilation
 - Background: ECMWF analysis
 - Result: global climate analyses, high-vertical/low-horiz. resolution (T21L60)

GNSS-CLIMATCH – First Results

“Testbed” Performance Analysis (JJA 1997)

GNSS-CLIMATCH Objective:

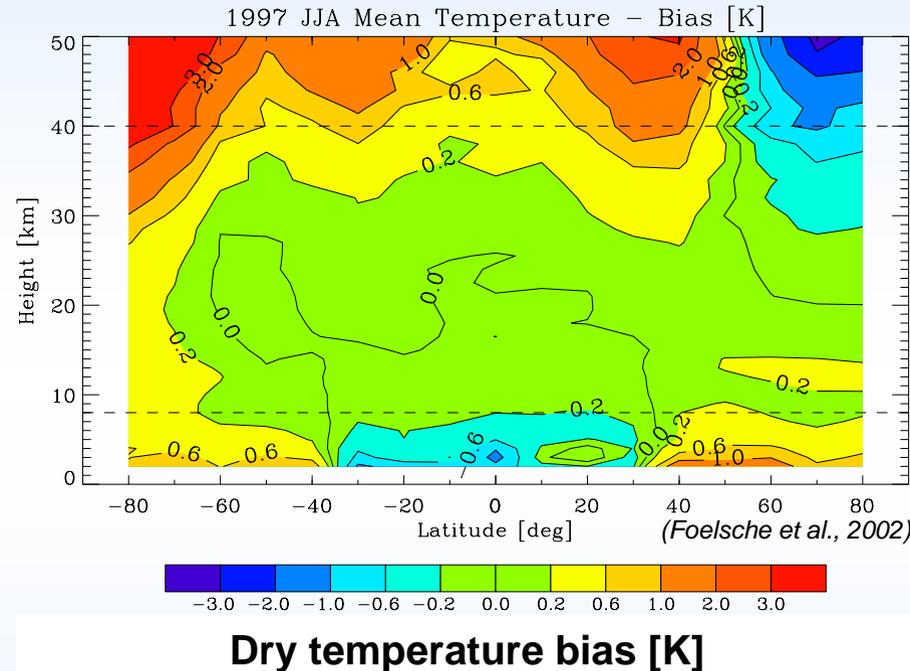

Investigation of climate change detection capability of RO-based climate monitoring systems

Method:

25 year end-to-end simulation study

Testbed setup:

- ~1000 occ. events/season (from >20000)
- Separation into 17 latitude bins (50-60 events each)
- Calculation of bias, standard deviation, sampling error, total climatological error

Results:

- Encouraging performance in the core region (bias < 0.2 K in most parts)
- high-latitude winter areas most challenging
- Error increases rapidly above ~35 km

RO Retrieval Overview

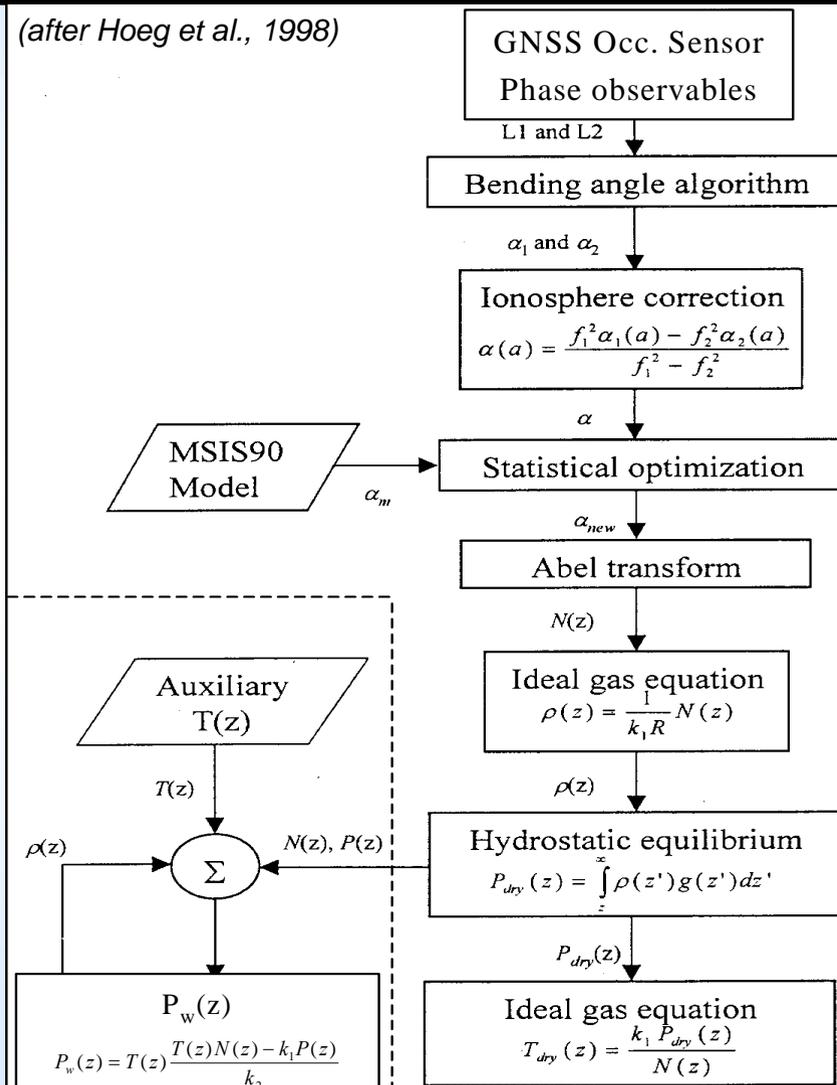

- Primary observable: L1, L2 phase delay
- Bending angle via Doppler shift
- Ionospheric correction & statistical optimization
- Refractivity via inverse Abel transform
- Density, pressure, temperature, geopotential height via ideal gas equation and hydrostatic equilibrium
- Troposphere: Temperature & humidity via a priori information.

Inverse Abel transform:

$$N(a) = \exp \left[\frac{1}{\pi} \int_a^{\infty} \frac{\alpha(a')}{\sqrt{a'^2 - a^2}} da' \right]$$

→ high altitude errors propagate downwards

(after Hoeg et al., 1998)

(Water Vapor, z < 8km)

Dry Temperature, 2km < z < 50km used

Ionospheric Correction

FACTS

- RO signal is dominated by ionosphere above ~45 km
- Ionosphere is dispersive → First order correction by linear combination of L1 and L2 phase delays or bending angles possible
- Linear combination of bending angles accounts for different L1 and L2 ray-paths → Better results.

$$\alpha_{LC}(a) = \frac{f_1^2 \alpha_1(a) - f_2^2 \alpha_2(a)}{f_1^2 - f_2^2}$$

“linear correction of bending angles”

(Vorob'ev and Krasil'nikova, 1994)

PROBLEMS

- Higher order terms cause residual ionospheric errors
- Linear correction of bending angles relies on the assumption of spherical symmetry

→ QUESTIONS

- How good is the performance of the linear correction of bending angles under violation of the spherical symmetry assumption?
- How to deal with higher order residuals?

Statistical Optimization (1)

FACTS

- Ionospheric residuals and observation system errors can significantly degrade the retrieval results at heights above ~25 km
- Inverse Abel transform needs high-altitude initialization

“NO OPTIMISATION”

- select initialisation height at ~60km
- exponentially extrapolate

Drawback:

- extrapolation quality depends on noise in the data and on initial height selection
- isothermal atmosphere assumed above initialization height

STATISTICAL OPTIMISATION

- Use background data (climatology, analyses)
- Combine background and observation in an statistical optimal way

$$\alpha_{opt} = \alpha_b + (\mathbf{B}^{-1} + \mathbf{O}^{-1})^{-1} \mathbf{B}^{-1} (\alpha_o - \alpha_b)$$

$$\alpha_{opt}(a) = \alpha_b(a) + \frac{\sigma_b^2(a)}{\sigma_b^2(a) + \sigma_o^2(a)} (\alpha_o(a) - \alpha_b(a))$$

(Sokolovskiy and Hunt, 1996)

Drawback:

- Stat. opt. approach assumes unbiased errors; background data are likely to be biased

Statistical Optimization (2)

Basic DMI/IGAM statistical optimization scheme

- **Background**

Climatology: MSIS90, no NWP analyses (bias and “incest” problems)

Global search in MSIS90 (45 - 65 km).

- **Definition of errors:**

$$\sigma_b(z) = 0.2\alpha_b(z)$$

σ_o estimated from observation at $z > 70\text{km}$

- **Vertically correlated errors:**

$$\mathbf{B}_{ij} = \sigma_i \sigma_j \exp\left(-\frac{(a_i - a_j)^2}{l^2}\right), \quad l = 6 \text{ km (correlation length)} \quad (\text{Healy, 2001})$$

Same for \mathbf{O}_{ij} , $l = 1 \text{ km}$

Forward modeling

- **Ionosphere (NeUoG):**
 - 4 ionization levels (no ionosphere, $F_{10.7}=70$, $F_{10.7}=140$, $F_{10.7}=210$)
 - 3 ionospheric a/symmetry types (NICE, NASTY1, NASTY2)
- **Same neutral atmosphere for all occultation events**
- **Receiving system:**
 - idealized (no errors)
 - realistic (GRAS-type errors)

Retrieval schemes

- **Ionospheric correction:**
 - linear combination of bending angles
- **Statistical optimization:**
 - no optimization (exponential extrapolation)
 - inverse covariance weighting optimization **without** background profile search in MSIS90)
 - inverse covariance weighting optimization **with** background profile search in MSIS90)

Gobiet, A., and G. Kirchengast, Sensitivity of atmospheric profiles retrieved from GNSS occultation data to ionospheric residual and high-altitude initialization errors, *Tech. Rep. ESA/ESTEC-1/2002*, 58p., IGAM/UniGraz, Austria, 2002.

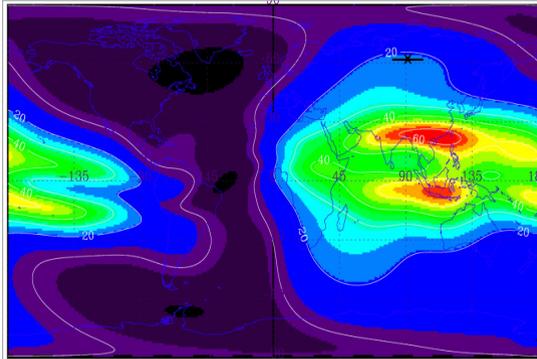

Advancement of GNSS RO Retrieval in the Upper Stratosphere

Retrieval Validation – Study Setup (2)

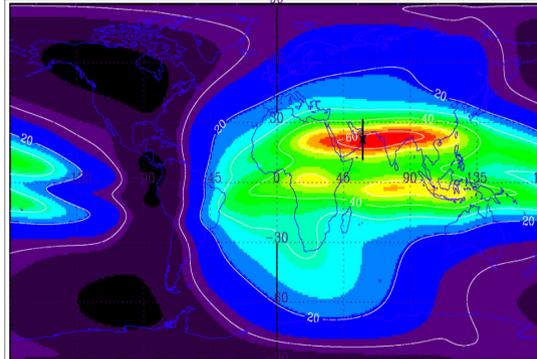

3D Ionosphere/UG F10.7=140 NICE
Vertical TEC [$10^{16}/\text{m}^2$]

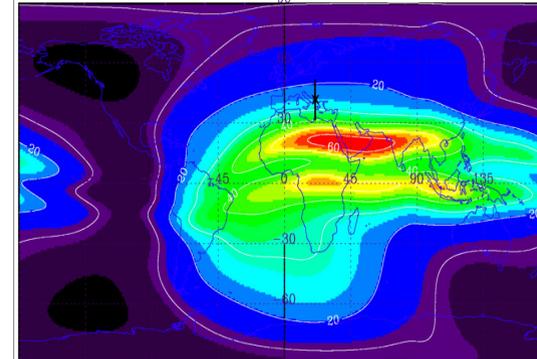

Produced by IGDFP/IGAM/UG et al. 1987-2001

3D Ionosphere/UG F10.7=140 NASTY 1
Vertical TEC [$10^{16}/\text{m}^2$]

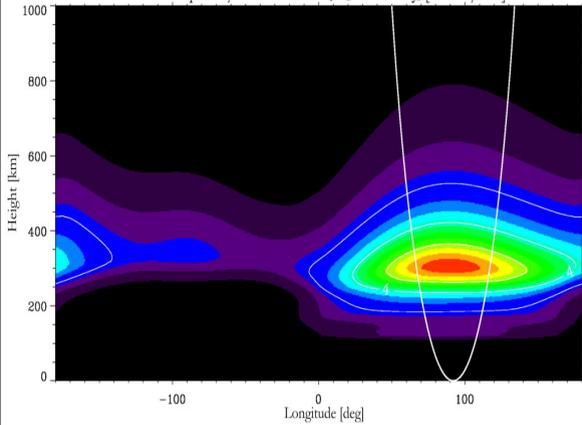

Produced by IGDFP/IGAM/UG et al. 1987-2001

3D Ionosphere/UG F10.7=140 NASTY 2
Vertical TEC [$10^{16}/\text{m}^2$]

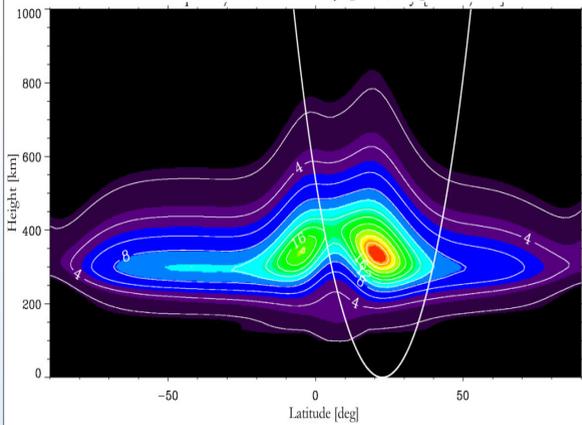

Produced by IGDFP/IGAM/UG et al. 1987-2001

Electr. Density [$10^{11}/\text{m}^3$]

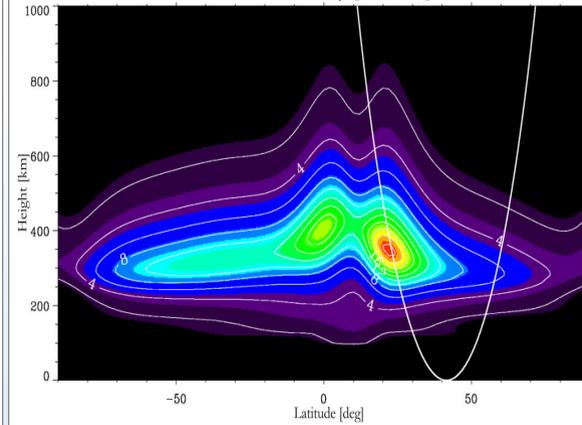

Produced by IGDFP/IGAM/UG et al. 1987-2001

Electr. Density [$10^{11}/\text{m}^3$]

Produced by IGDFP/IGAM/UG et al. 1987-2001

Electr. Density [$10^{11}/\text{m}^3$]

Produced by IGDFP/IGAM/UG et al. 1987-2001

NICE: low electron dens. grad., near-spherical symmetry

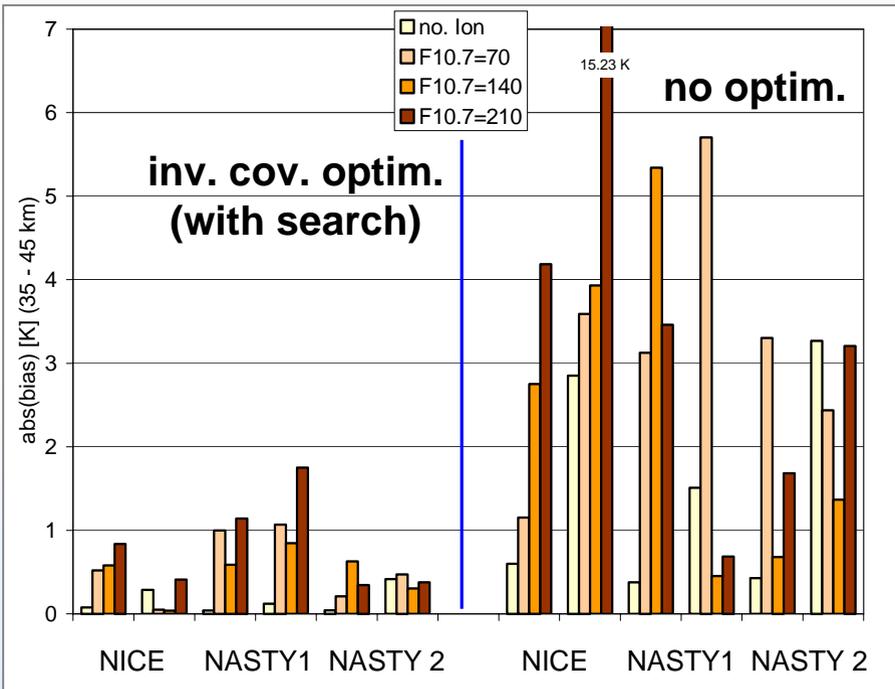

NASTY1 & NASTY2: high electron density gradients, spherical symmetry assumption violated

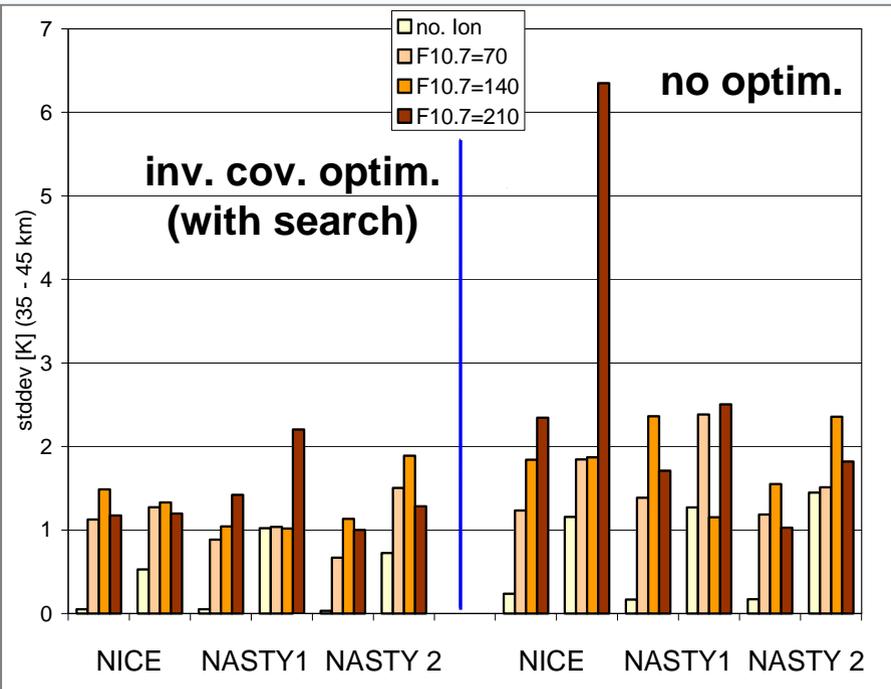

Retrieval Validation – Results (1)

Upper stratosphere temperature bias and standard deviation (35 km – 45 km height interval)

bias (mean dev. from 'true')
[K]

standard dev. (mean fluctuation about bias)
[K]

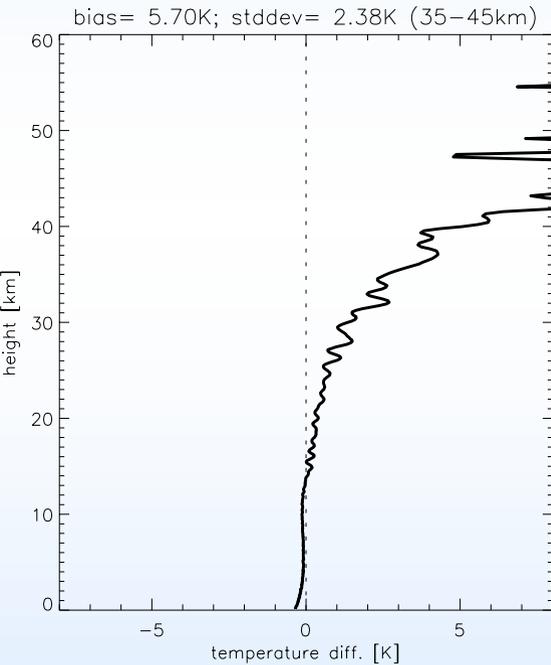

Retrieval Validation – Results (2)

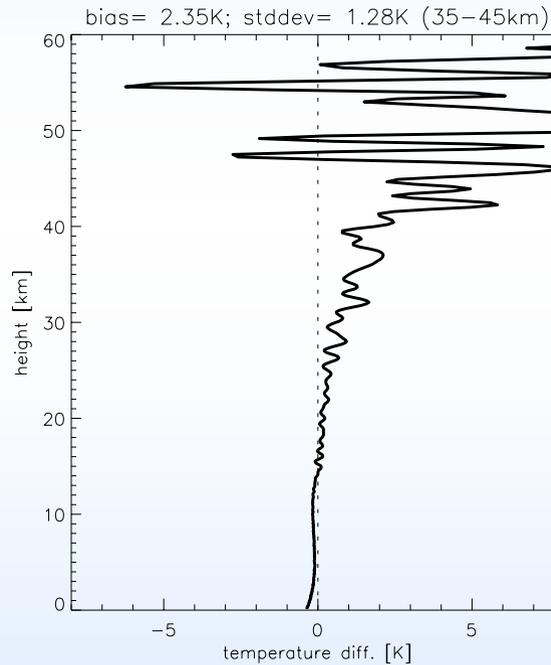

Temperature error profiles [K]

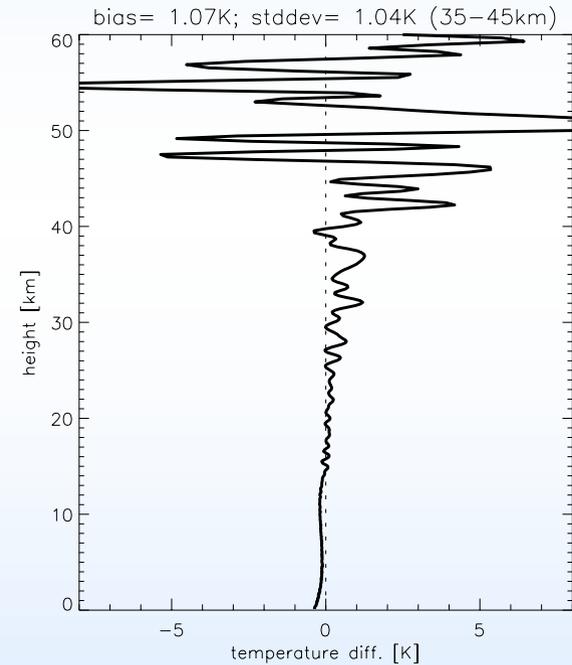

(“Nasty 1” event, $F_{10.7} = 70$, realistic receiving system)

no optimization

**inverse covariance optim.
no background search**

**inverse covariance optim.
background search**

Validation Results – Summary

- Ionospheric correction of bending angles is robust against extreme ionospheric conditions
- Statistical optimization is vital above ~25 km
- Statistical optimization is limited to bias-free observation and background errors but background errors are rather systematic than statistical
- In some regions no unbiased background profiles can be found in MSIS90 (high latitude winter)

→ advanced background bias correction

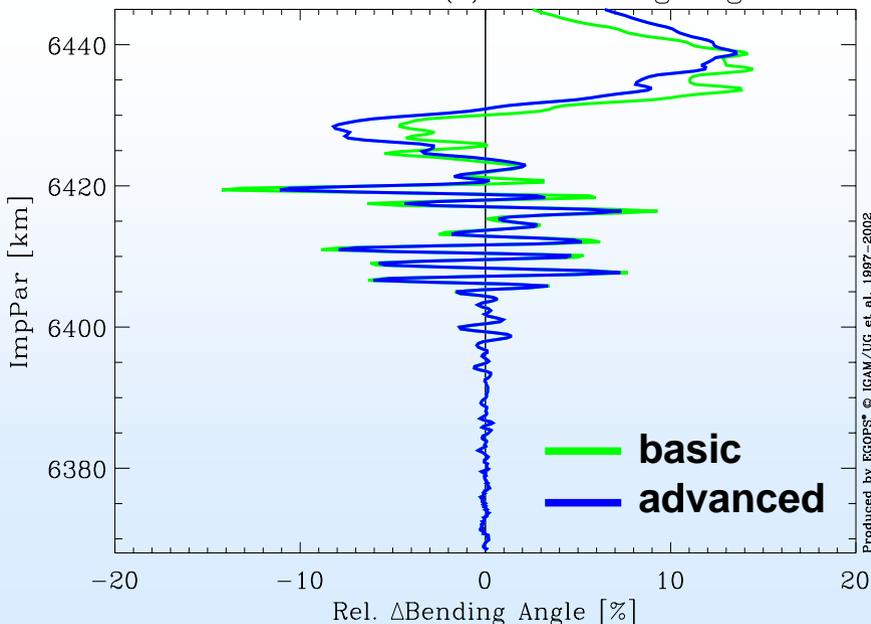

Background Bias Correction

ENHANCED BACKGROUND BIAS CORRECTION SCHEME

- Optimization of the search algorithm by smoothing of observations
- Additional background bias correction by linearly fitting at high altitude
- Reduce background error to 15% (empirical evaluation preceded)
- Background: MSIS90

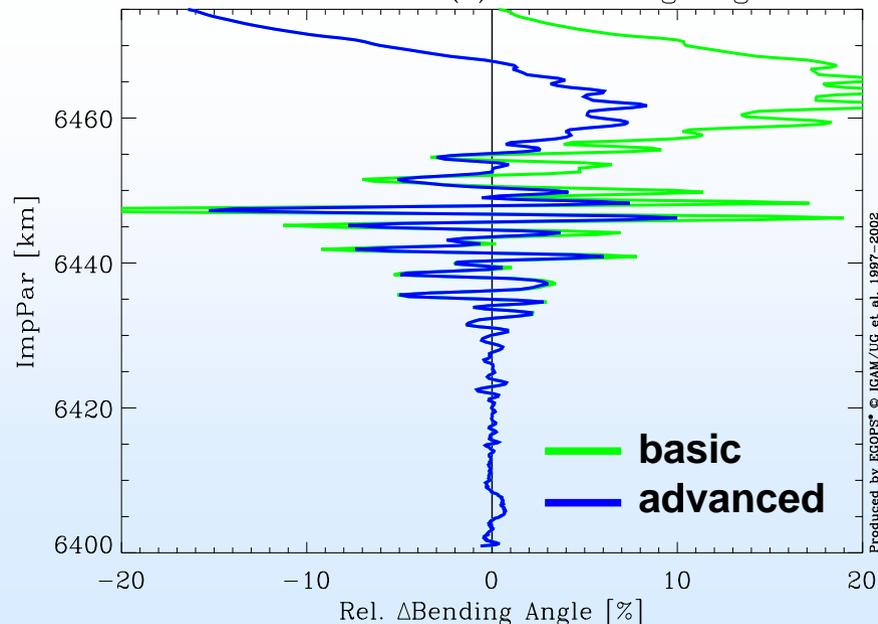

lat. = 13°S, bias correction: 0.2 %

Rel.Diff. Profile(s) of Bending Angle

lat. = 76°S, bias correction: 15.9 %

Rel.Diff. Profile(s) of Bending Angle

~1000 occultation events)

Summary, Conclusions & Outlook

High altitude retrieval validation

- Statistical optimization is vital above ~25 km
- Ionospheric correction of bending angles is robust against extreme ionospheric conditions
- Most critical: Biases in background data

Enhanced background bias correction scheme

- Empirical background bias correction
- Very effective, especially in the so far most critical regions

Outlook

- Retrieval performance study based on CHAMP data
- Further retrieval development:
 - background & observation error definition
 - lower tropospheric retrieval
- First RO-based climatologies are on their way . . .
