

Overview on GRAS Raw Sampling and Data Quality Aspects

C. Marquardt
and the GRAS Raw Sampling Study Team

Outline

- A bit off-topic: GRAS (and Metop) after 2012
- Issues with GRAS data quality
- 2 Studies
- EUMETSAT's FSI
- Summary & Outlook

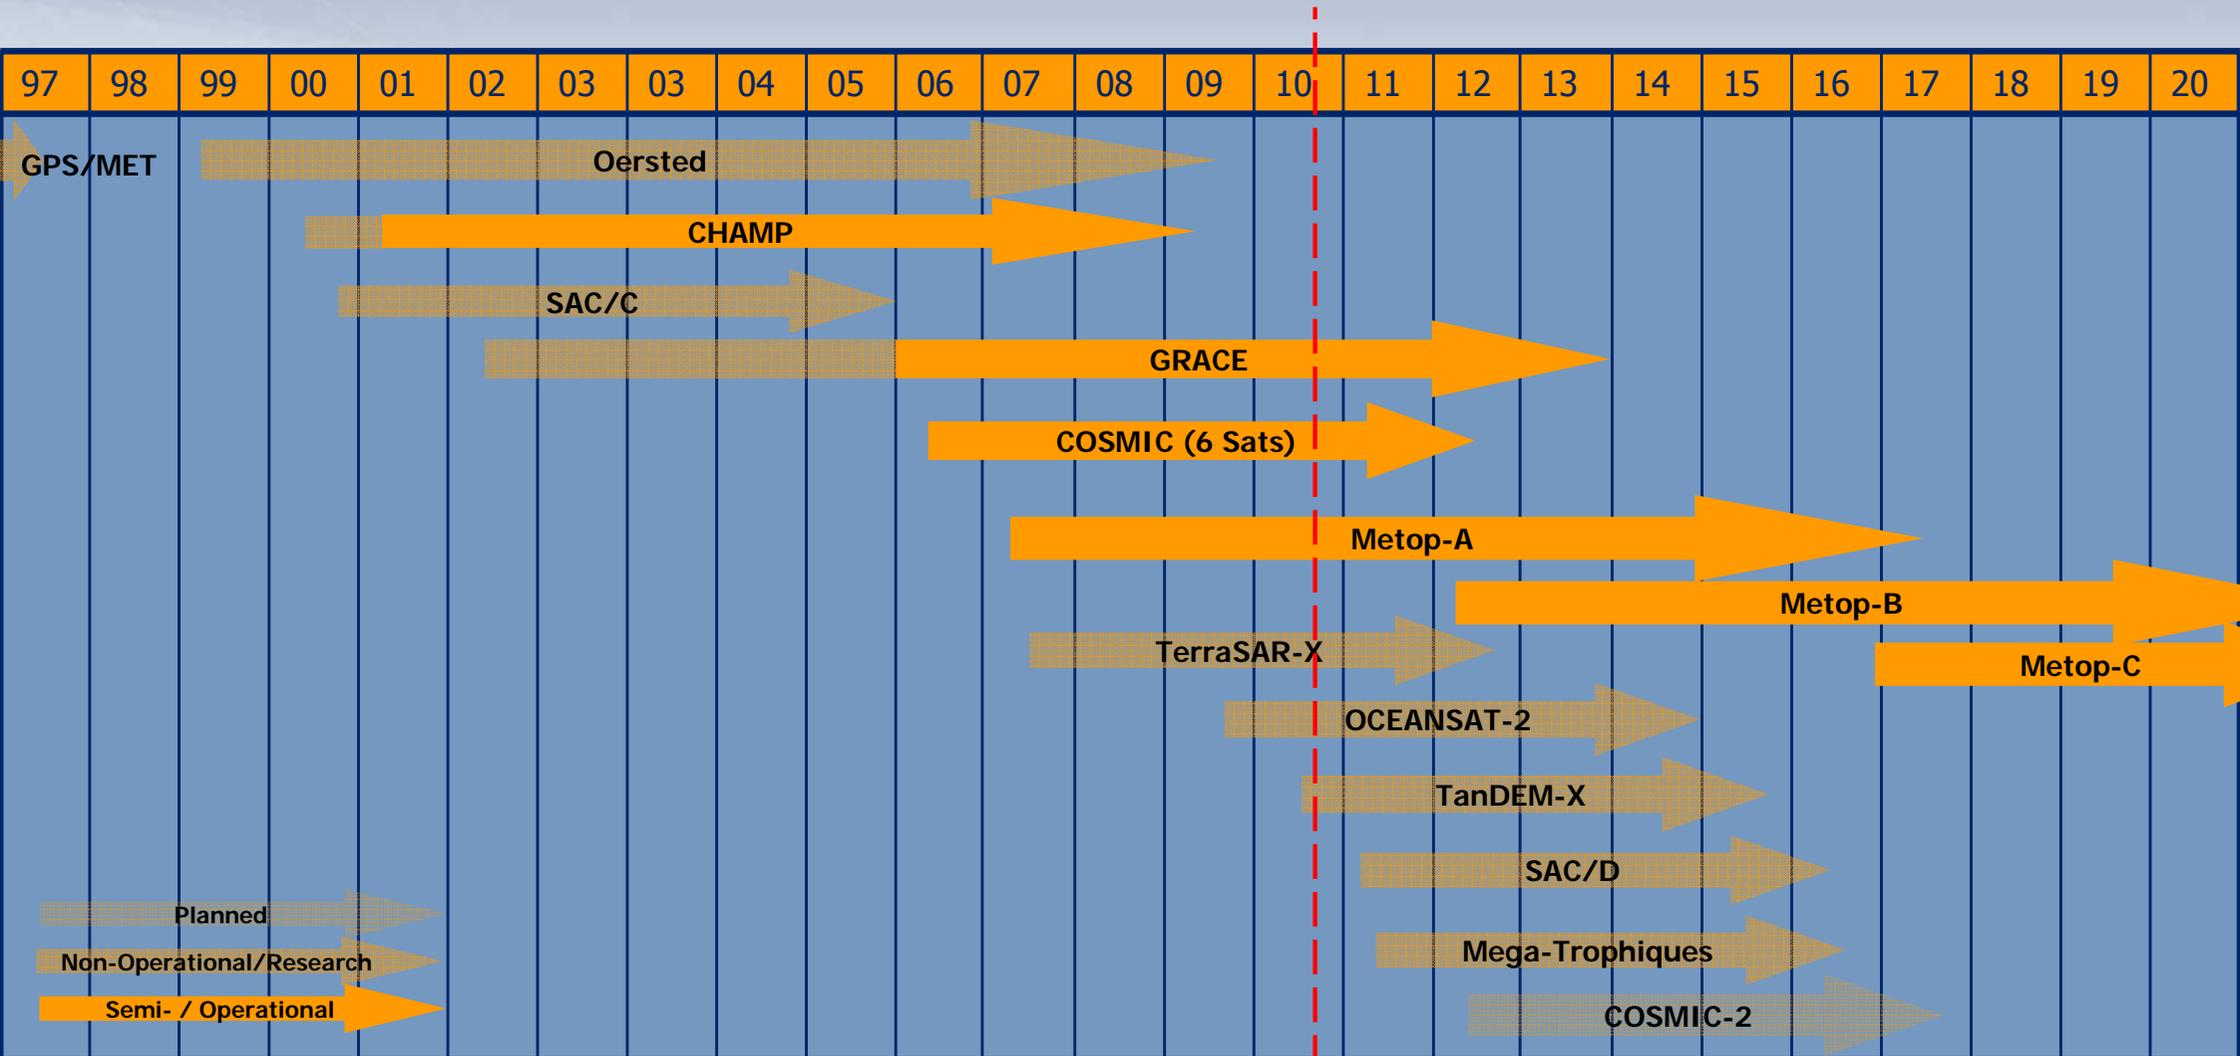

GRAS on Metop

GRAS on Metop: EPS

- Metop-A is the first of three satellites in the European Polar System (EPS)
- Europe's contribution to the Initial Joint Polar-Orbiting Operational Satellite System (IJPS)
- Into 2020's, with identical instruments on each S/C (except for HIRS)
- GRAS (GNSS Receiver for Atmospheric Sounding)
- 1st custom build GPS receiver for operational RO

GRAS on Metop: Instruments Overview

now

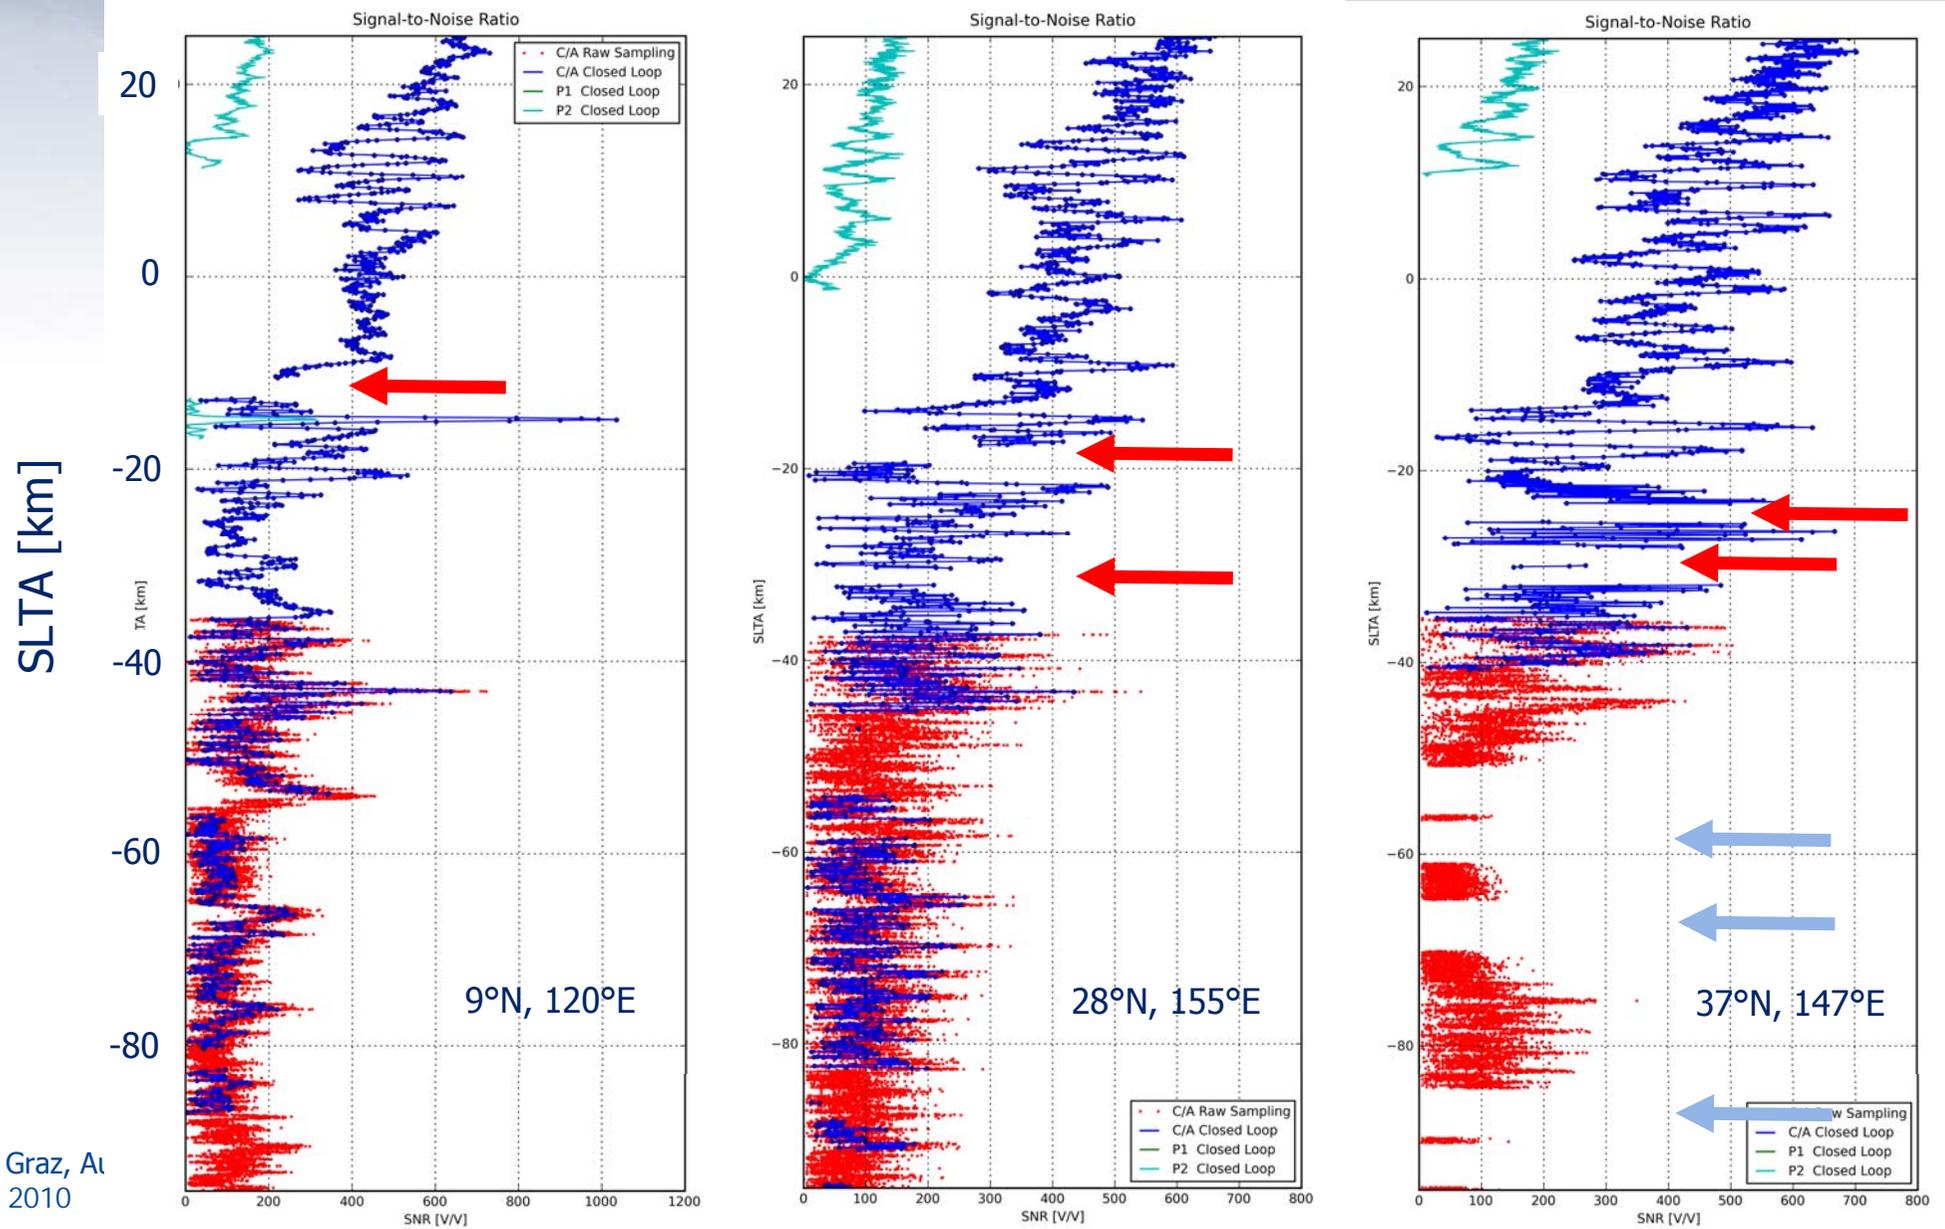

Issues in GRAS data

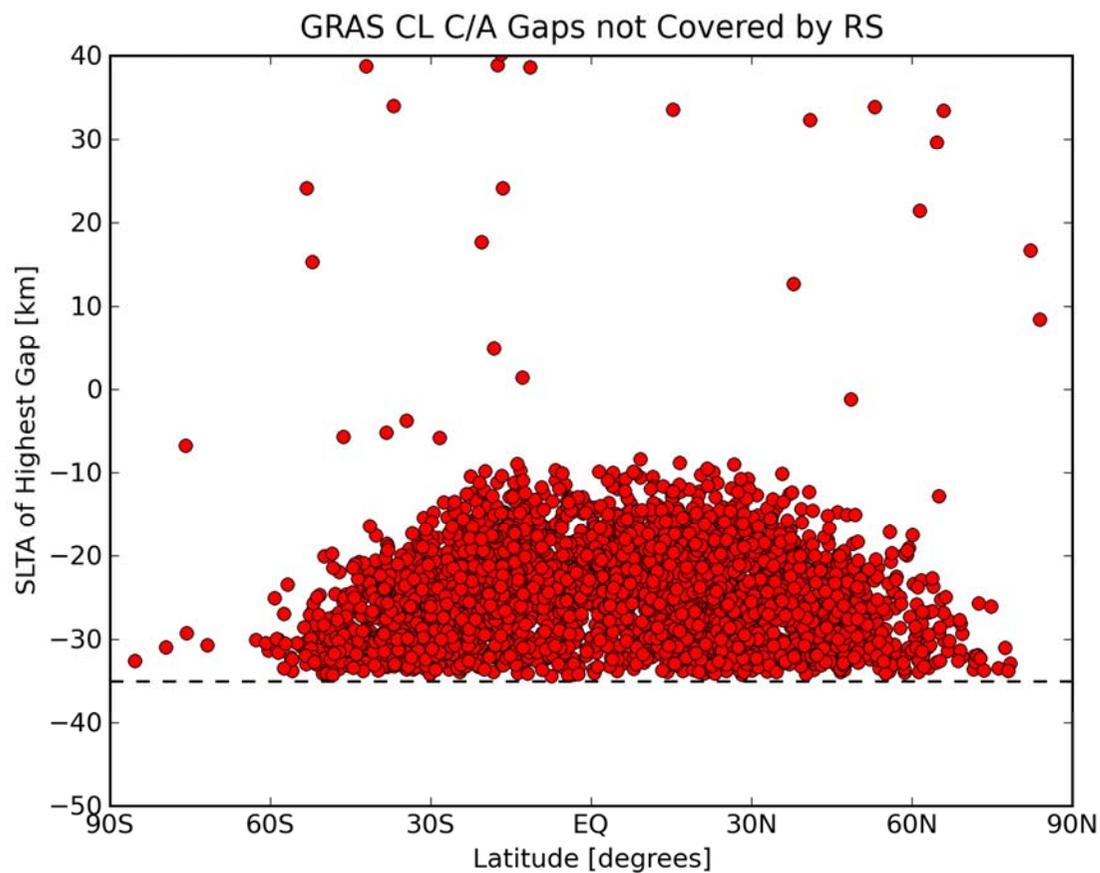

Raw Sampling

- **Dual Frequency Carrier Tracking:** code and carrier for L1 and L2 are tracked; both (+ C/A) are reported @ 50 Hz
- **Single Frequency Carrier Tracking:** C/A code and carrier phase are tracked; C/A code and carrier are reported @ 50 Hz
- **Single Frequency Raw Sampling:** C/A code tracked, 1 kHz sampling of carrier
- SF carrier tracking and raw sampling can occur simultaneously
- Either L2 or RS
- GRAS requires the C/A code being tracked even in Raw Sampling mode
- Tracking state information available

Closed Loop Data Gaps in Rising Occ's

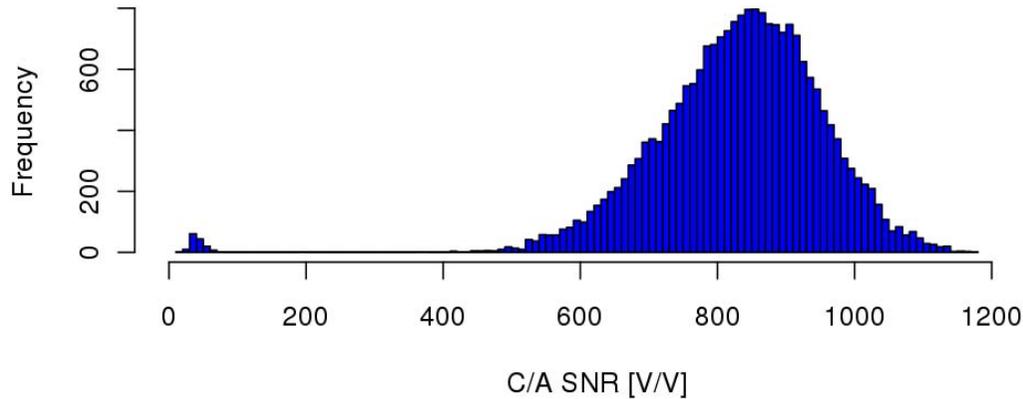

Closed Loop Data Gaps in Rising Occ's (cont'd)

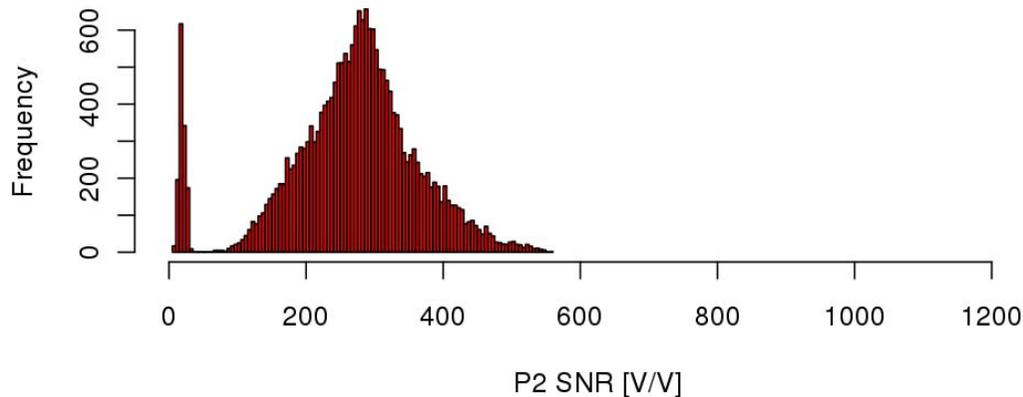

- SLTA of highest gap in C/A carrier phase data (from October 2007)
- About 33% of rising occultations are affected, 16% in total
- Will have to live with this in "historic" data; workarounds and maybe a fix in the GRAS firmware in the future
- In addition: most occultations have gaps in the RS part due to C/A code tracking losses

Low L2 SNR

C/A Signal-to-Noise Ratios

P2 Signal-to-Noise Ratios

- C/A SNR < 200 for $\leq 1\%$ of all occultations
- P2 SNR < 50 for $\leq 7\%$ of all occultations
- no relation to rising/setting
- Magnus says: GRAS tracks wrong portion of the code
- in effect: large number of cycle slips in L2 phase data
- Retrievals are either significantly noisier, or not useful at all; will flag these profiles as 'bad'

Studies

Note: We will concentrate on bending angles in the following...

ESA Study on GRAS Data Quality (21995/08/NL/EL)

Formal study team:

RUAG (talk by Magnus)

DMI (talk by Kent)

Uni Graz

DLR (POD)

ESA/ESTEC

EUMETSAT

supported by

Michael Gorbunov (GRAS SAF visiting scientist)

Arne Jensen (EUM visiting scientist)

and even by (without funding – thank you *very* much!)

GFZ Potsdam (poster by Florian)

Study aims:

- Validation of reconstructed GRAS amplitude and phase data (RUAG was happy with us at the end;-)
- Initial assessment of GRAS performance and different advanced retrieval algorithms in the troposphere

Note:

- All results of this study are based on the same level 1a data set (and orbits) produced by EUMETSAT
- Possible retrieval differences highlight structural uncertainties in the level 1b processing

EUM Study on Structural Uncertainty in RO Retrievals

Study team:

UCAR (talk by Chris)

EUMETSAT

Study aims:

- Structural uncertainty issues in low level reconstruction
- EUMETSAT wanted to initiate / support
 - GRAS data reconstruction independent from EUMETSAT
 - offline or even operational processing of GRAS data outside of EUMETSAT

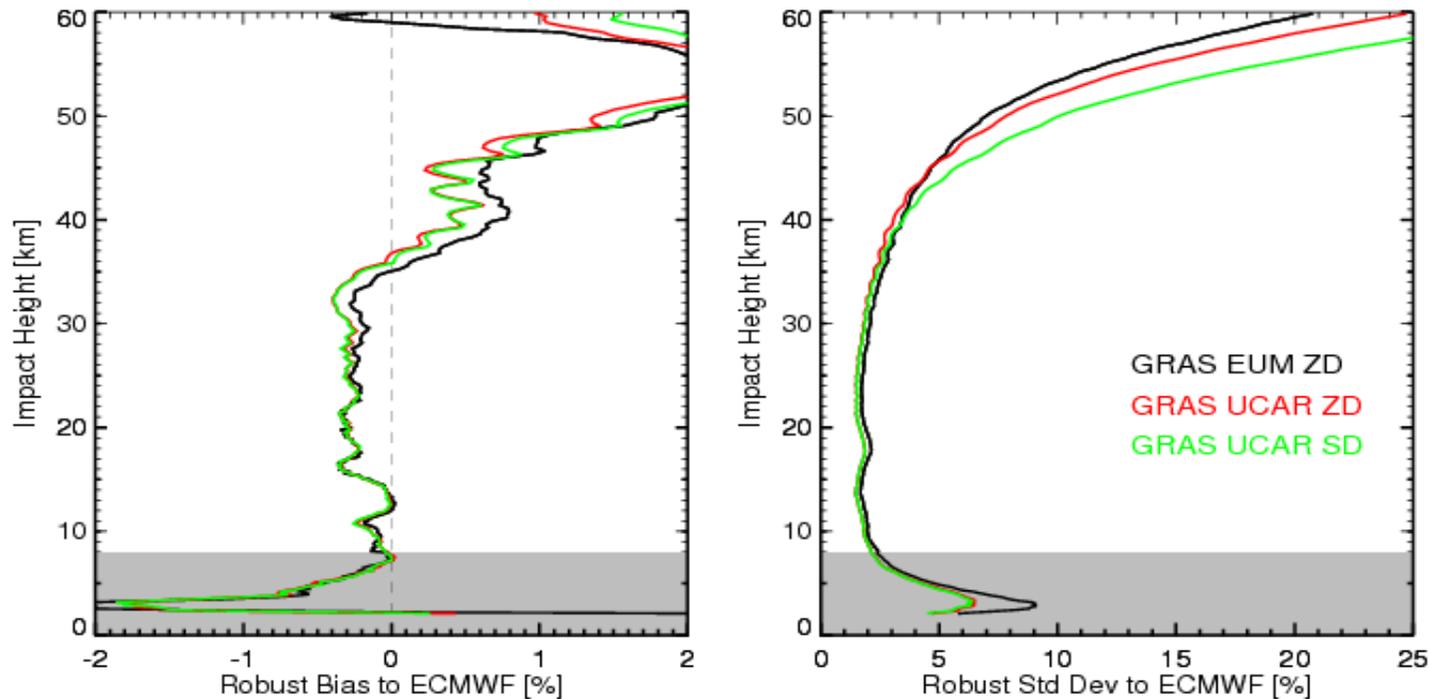

Note:

- Initially targeted GO retrievals only, but UCAR proposed an extension (with DMI) to study tropospheric data as well – will start in November (but see early work in Doug's talk)
- UCAR developed their own GRAS reconstruction system and used their own orbits (but had visibility of the EUMETSAT prototype)
- Possible retrieval differences highlight structural uncertainties in both level 1a and level 1b processing (and POD)

EUM/UCAR Study on Structural Uncertainty

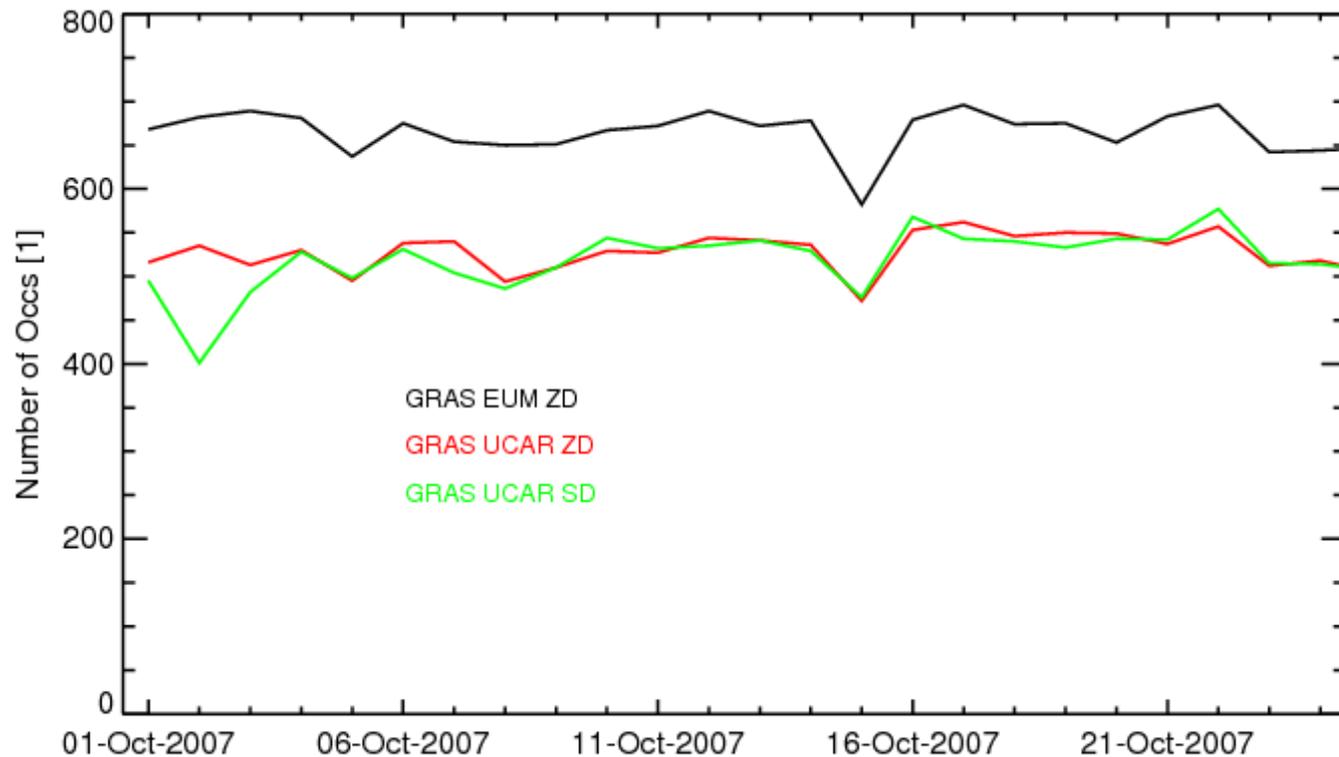

GRAS Statistics vs. ECMWF

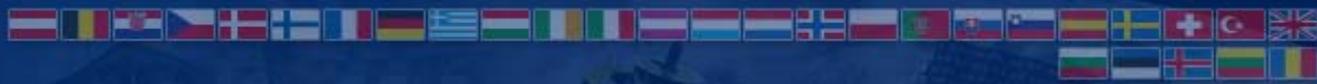

- UCAR based processing of GRAS data (Oct 2007)
- EUMETSAT provided prototype processor for guidance
- ZD: Zero differencing, SD: Single differencing.
- Grey shaded area indicates GO-related limitation due to multipath.

Note: The bias structure GRAS/UCAR and GRAS/EUM is interesting; we see a similar one between COSMIC/EUM and GRAS/EUM.

Number of Occultations

- UCAR based processing of GRAS data (Oct 2007) including independent POD and level 0 reconstruction
- ZD: Zero differencing, SD: Single differencing.
- UCAR certainly applies a strict QC to the profiles they deliver (15% of profiles less than what's available)

ESA Study on GRAS Data Quality

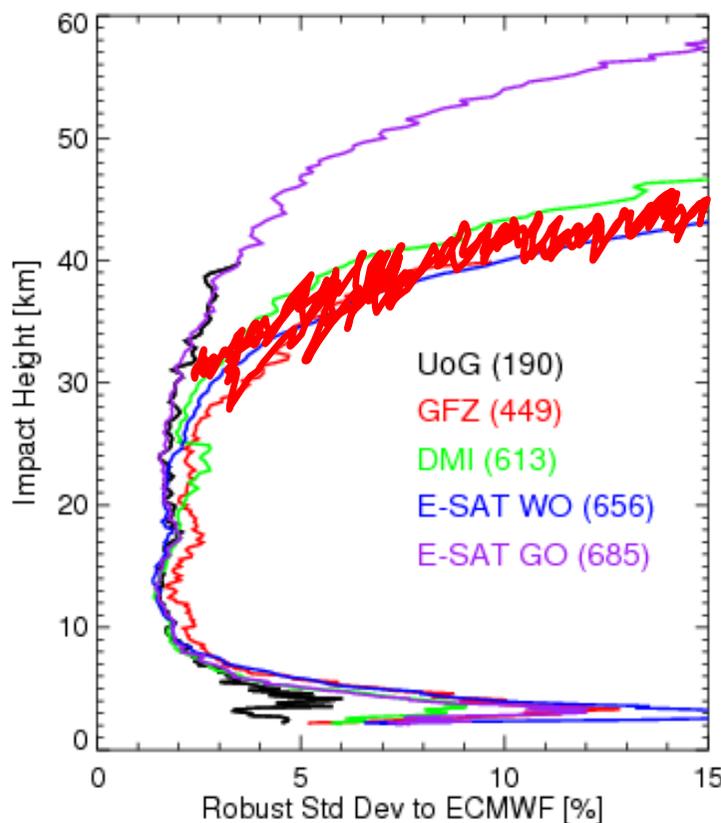

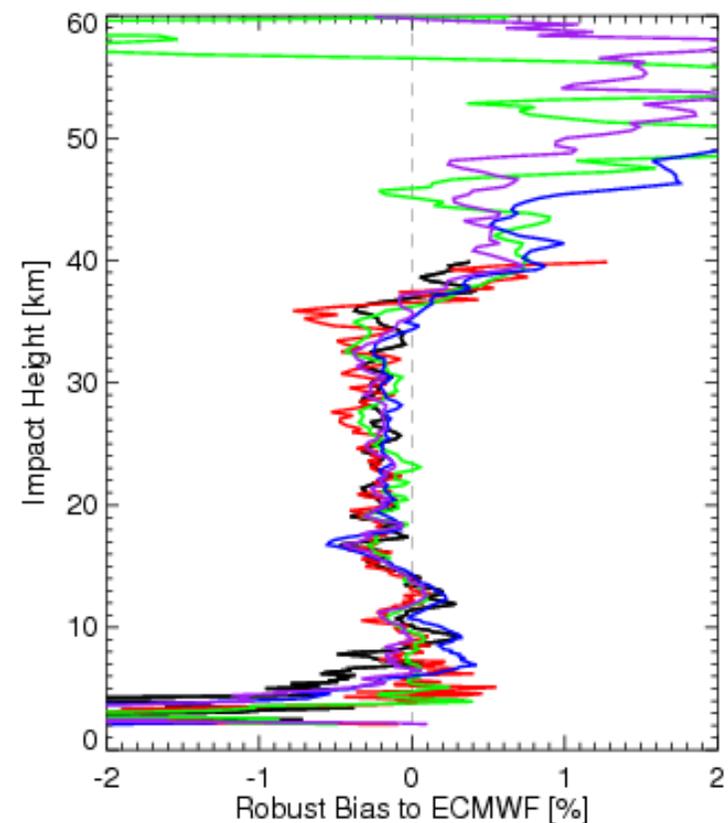

Study Period and Special Thanks

- Study period: 30. September 2007 – 31. October 2007
- Reconstructed (level 1a) data provided by EUMETSAT
- Special thanks for the provision of navigation bit data for this study:
 - Chris Rocken (UCAR – ~ 75% coverage)
 - Georg Beyerle (GFZ – ~ 75 % coverage)
 - Yoaz Bar-Sever (JPL – 100 % coverage)

Processing Setups

| Centre | Algorithms | Filter | Remarks |
|--------|--|--|--|
| DMI | CT2 < 25km, GO above FSI | radioholographic filtering; combined ionosphere & stat opt | missing navbits replaced by internal navbit estimates |
| GFZ | FSI < 12 km, GO above | GO: 40 points | only if external navbits are available iono correction requires L2 at certain altitudes |
| Graz | CT in troposphere, GO above GO only | | setting occs only |
| EUM | FSI everywhere GO only | altitude dependent GO: 75 points | internal navbit estimates fine tuning ongoing |

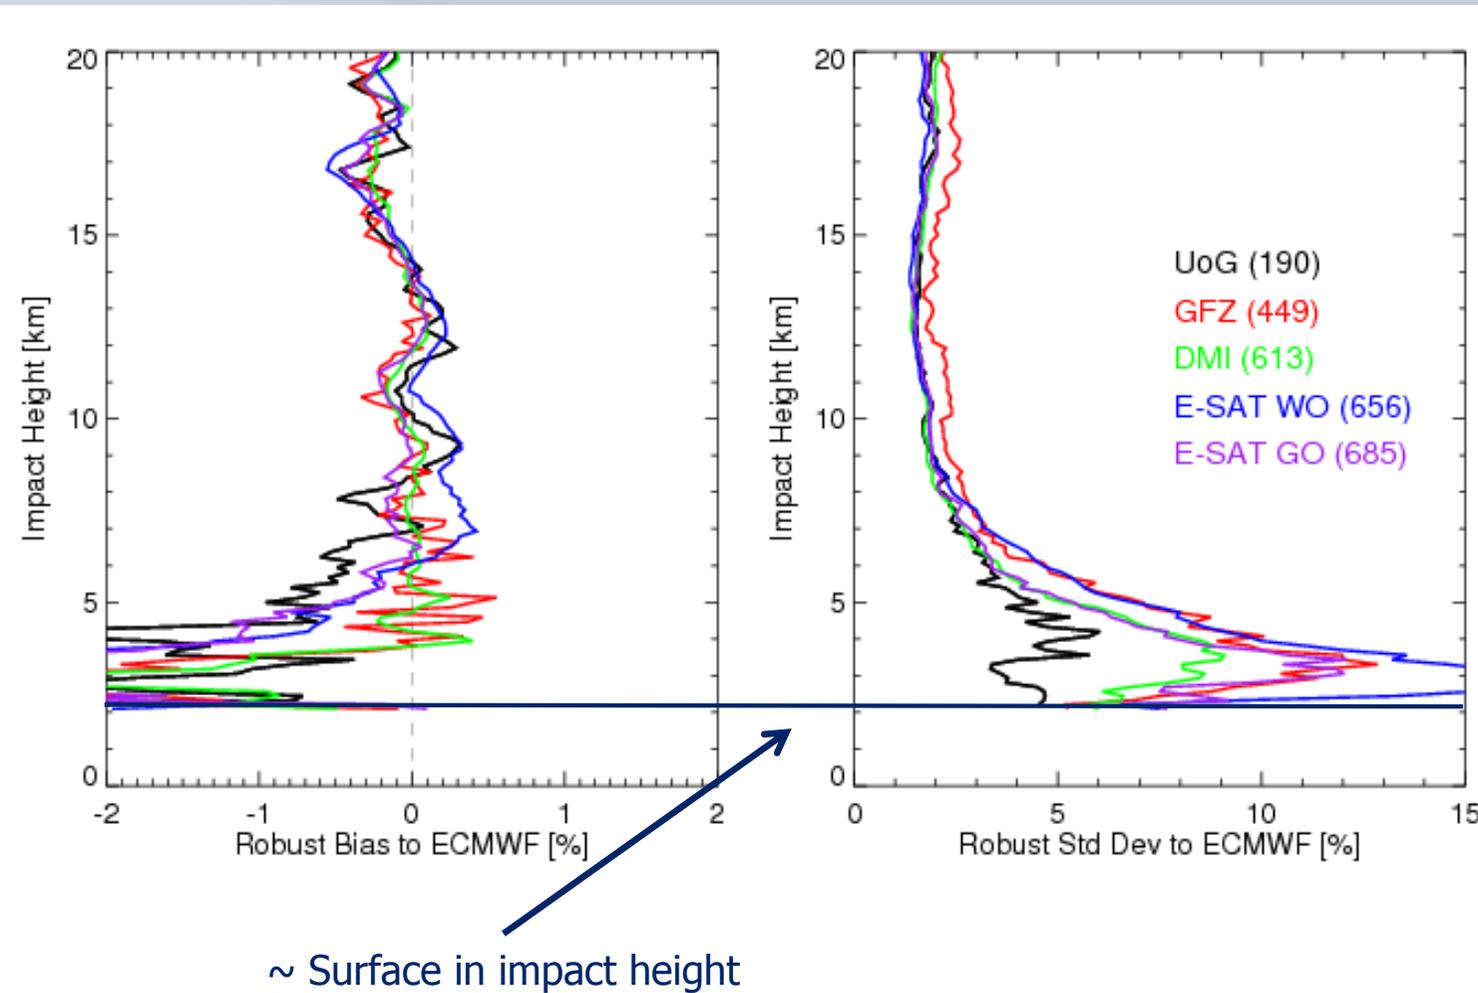

Stratospheric Bending Angles vs. ECMWF

Data from 30. Sep 2007

- All retrievals are based on identical level1a data!
- Biases above 40 km are a (known) ECMWF problem
- Biases between 15 and 35 km are also an issue in ECMWF data (and it's 0.2% only anyway...)
- Different numbers due to different processing options
- Different sdevs may reflect different filter settings in data preprocessing...
- ...or simply a bug in the orbit processing we discovered recently... :-((

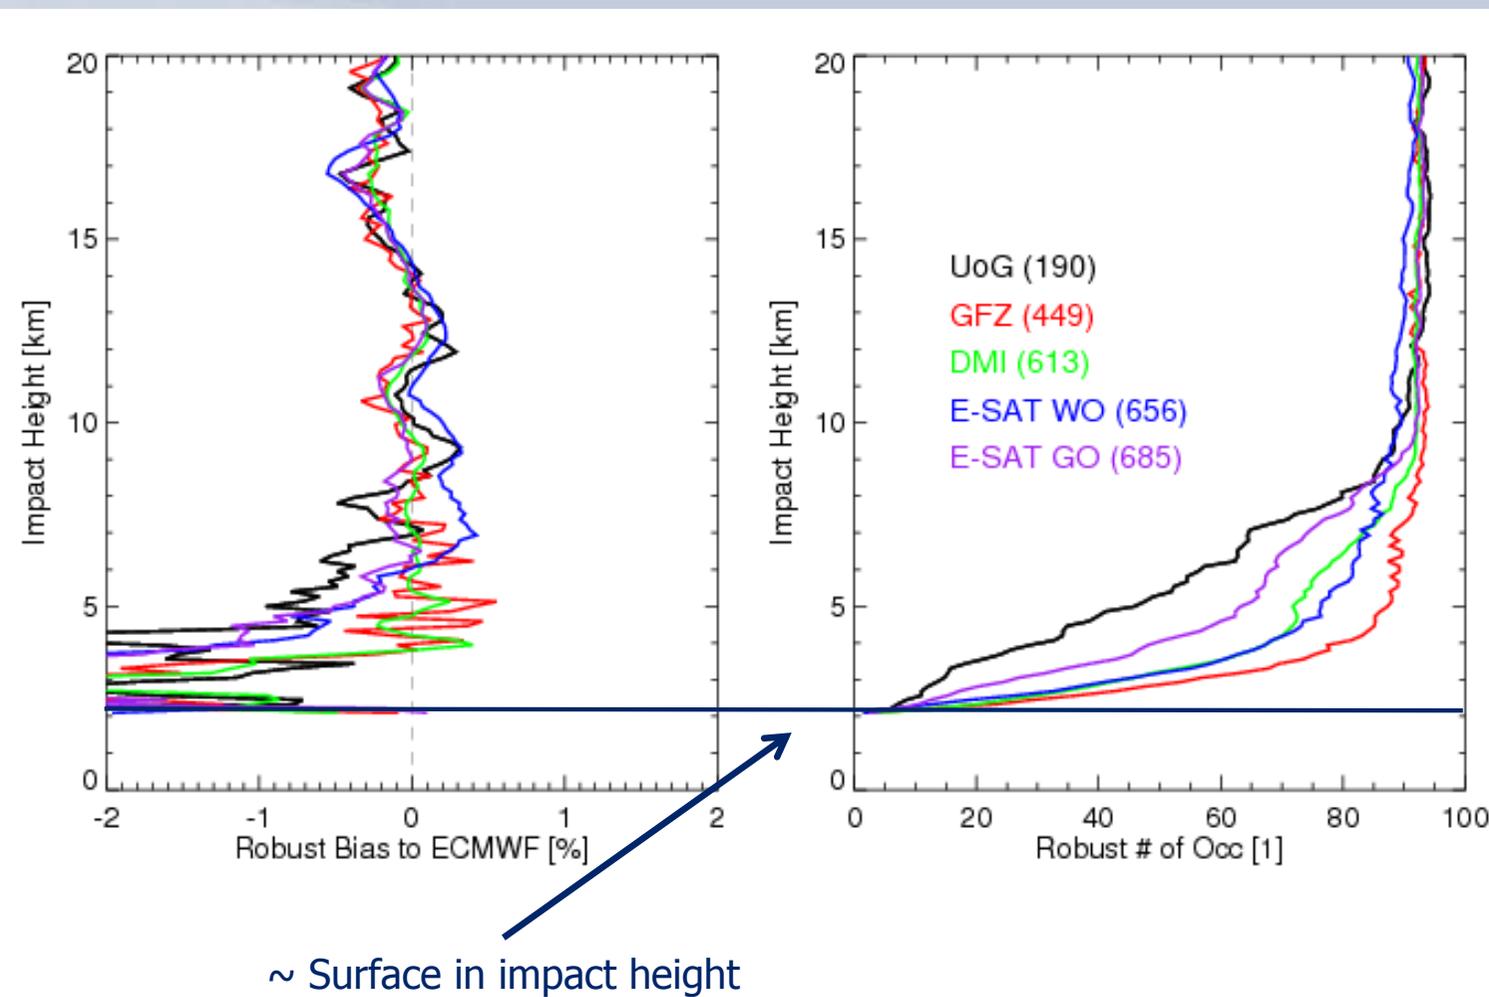

Tropospheric Statistics vs. ECMWF

- All retrievals are based on identical level1a data!
- Results above ~10 km impact height are all highly consistent; below it gets interesting...
- EUMETSAT FSI shows slightly positive bias between 5 and 10 km
- Below 3-5 km impact height (~2-3 km real height), negative biases prevail
- Different sdevs probably reflect different processing options (or bugs) as well...

Data from 30. Sep 2007

Tropospheric Statistics vs. ECMWF (cont'd)

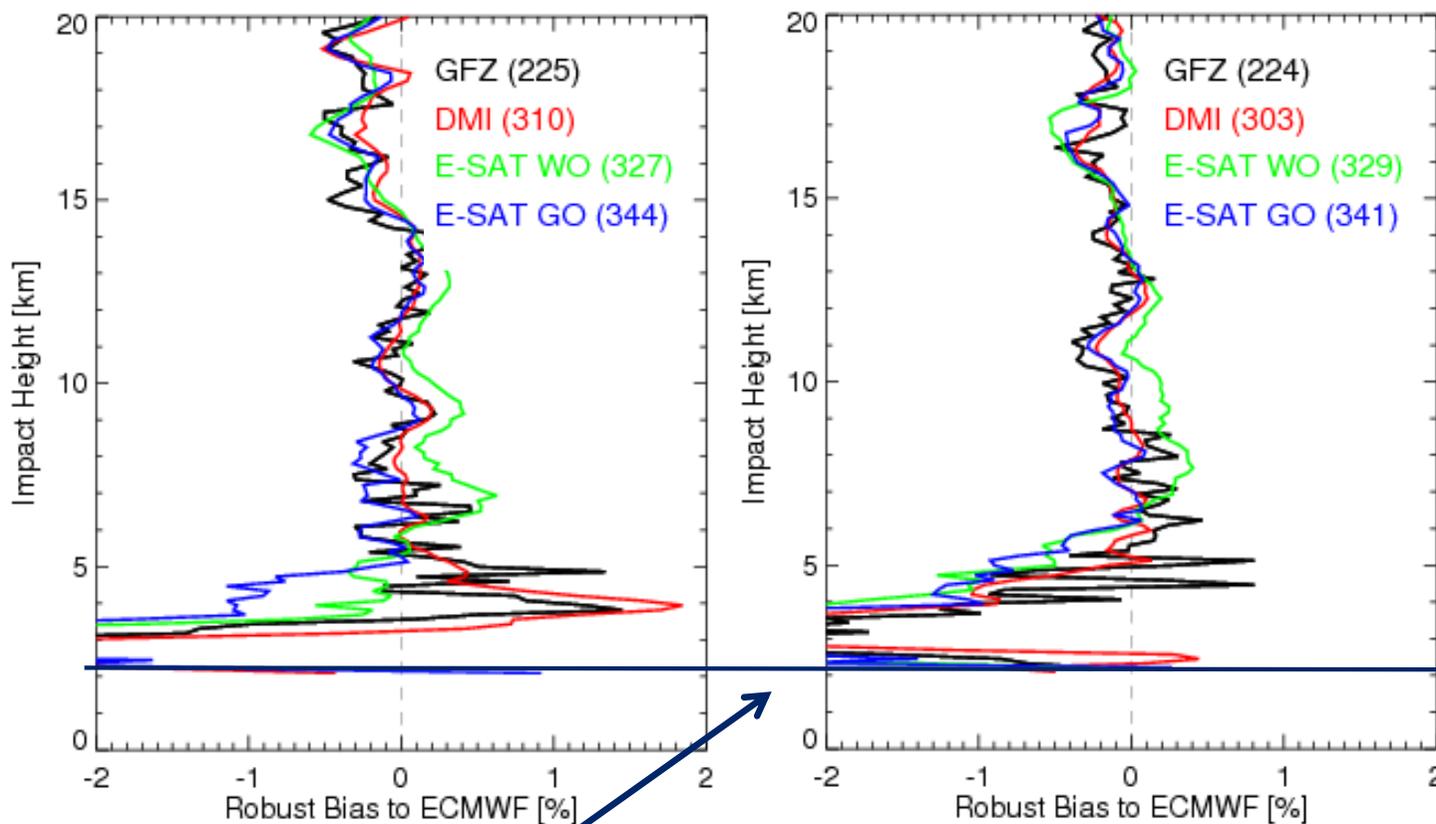

- All retrievals are based on identical level1a data!
- Retrievals below ~10 km impact height strongly depend on level 1b processing options:
 - Cut-off criteria for CT/FSI
 - Smoothing / Filtering
 - Data gap handling
 - QC
 - Navbits, ...
- General remark: We interpret ECMWF as a reference source for comparisons, *not* as truth.

Data from 30. Sep 2007

Tropospheric Statistics vs. ECMWF (cont'd)

00:00 – 12:00 UTC

12:00 – 24:00 UTC

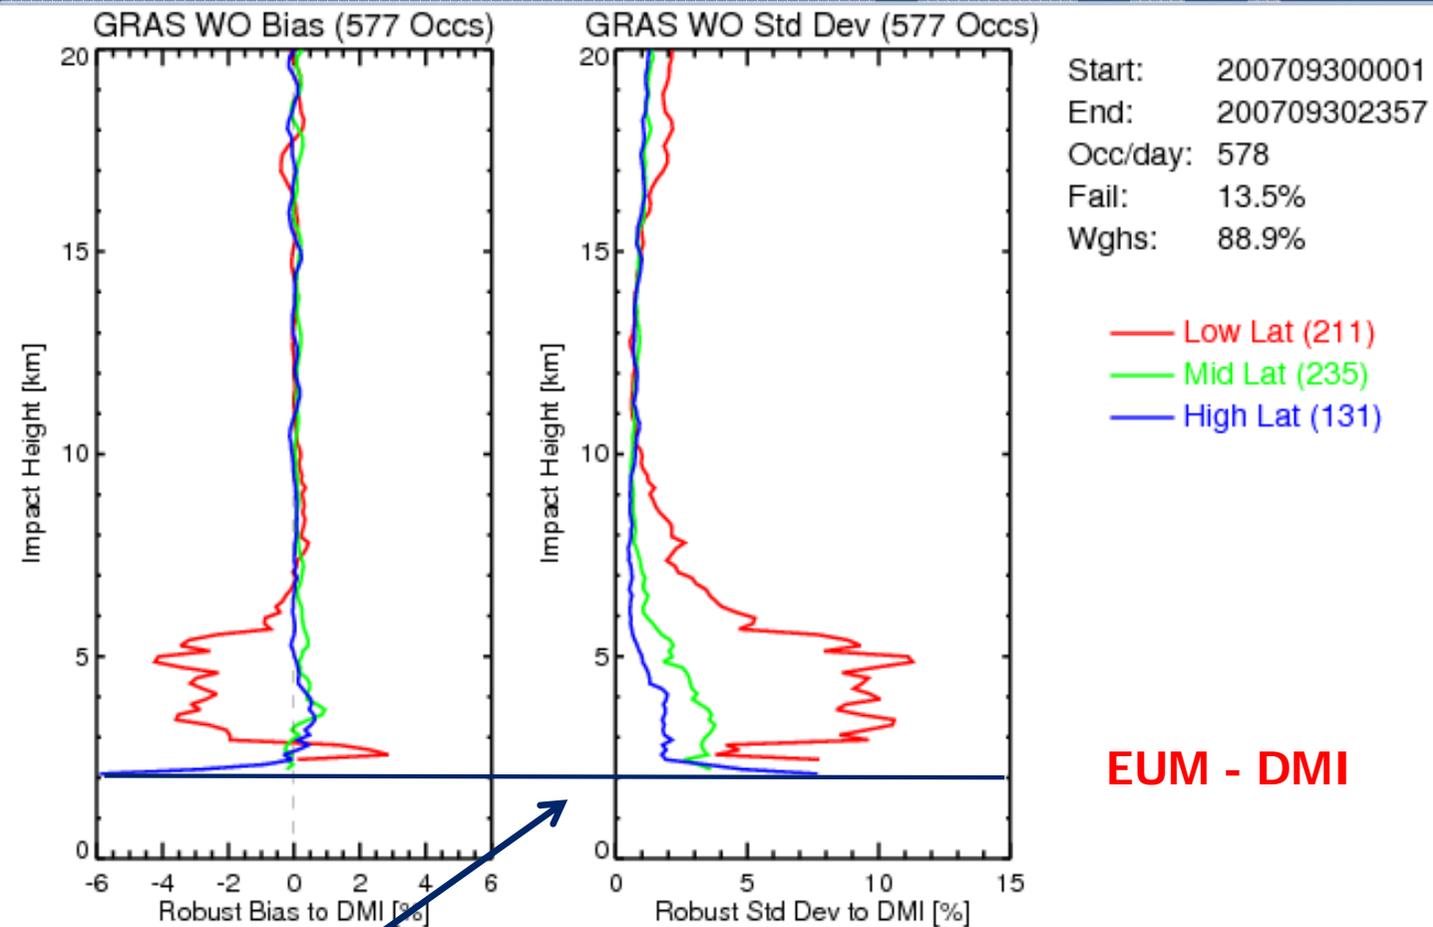

~ Surface in impact height

Data from 30. Sep 2007

- All retrievals are based on identical level1a data!
- A single day is hardly enough to draw conclusions based on statistics, obviously...
- General remark: We interpret ECMWF as a reference source for comparisons, *not* as truth.

Tropospheric Statistics – Matching Profiles

EUM - DMI

~ Surface in impact height

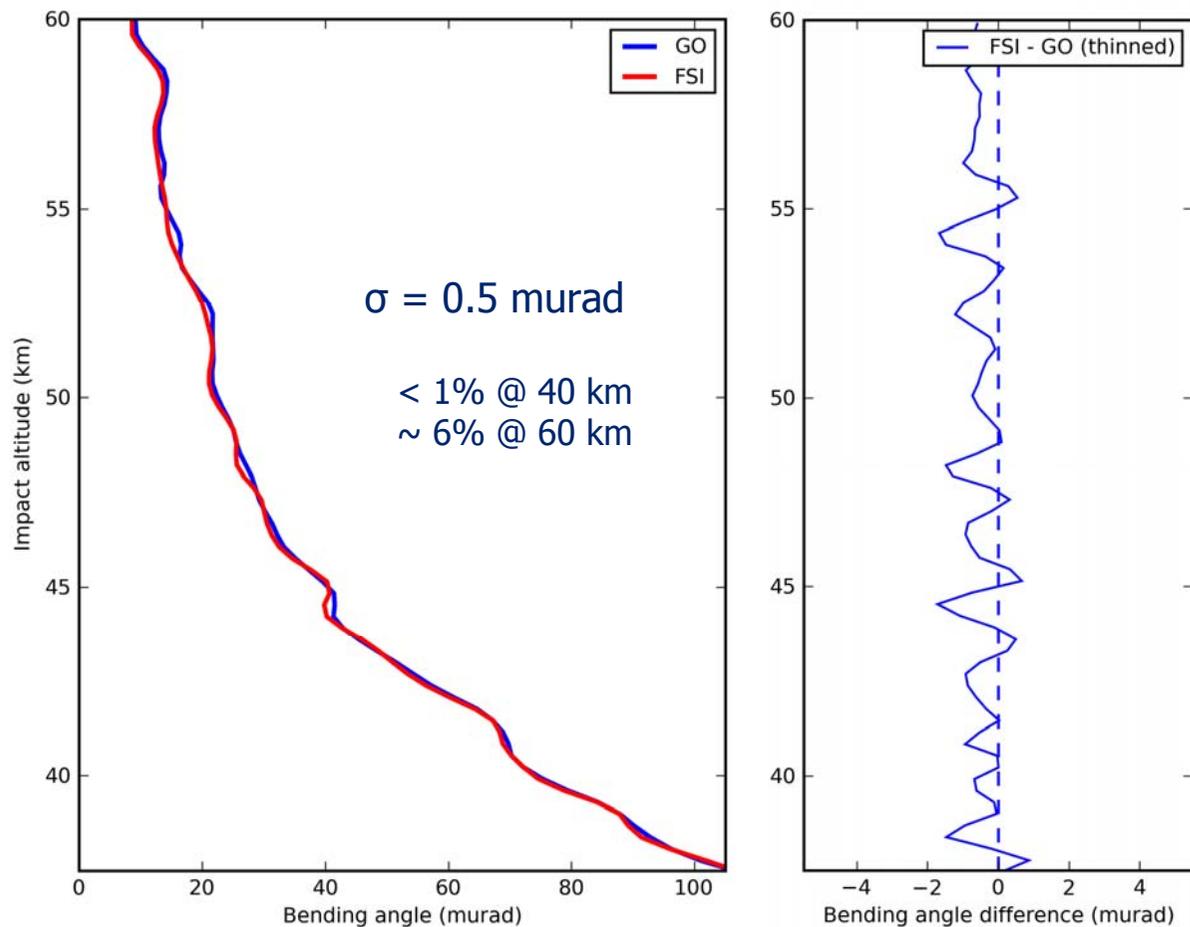

- All retrievals are based on identical level1a data!
- Profile-by-profile matching suggests :
 - reasonable or good agreement ($\leq 0.2\%$ bias / $\leq 1\%$ sdev) in mid/high latitudes and above altitudes affected by multipath in the tropics...
 - ...but significant structural uncertainties where humidity is abundant
- We need to look into that in more detail.

Data from 30. Sep 2007

EUMETSAT's FSI

FSI over the entire altitude range

Rising occultation on 30/09/2007 09:43 UTC, 60°E, 13°S

- Small vertical scale noise: finite differencing of the Fourier-transformed phase
 - Kaiser-Filter (Kaiser & Schafer, 1980) with a -100 dB stopband
 - doubling current filter width produces no systematic effects / biases
- Larger scale noise: variable bandwidth local polynomial regression filter (Loader, 1995; Wand & Jones, 1995) in impact parameter space
 - NWP / thinned data: tied to 247 level grid of thinned GRAS products, ~ 1 Fresnel diameter
 - Additional higher resolution profiles for science applications (TBD)
- FSI-GO deviations are in the order of GRAS bending angle noise

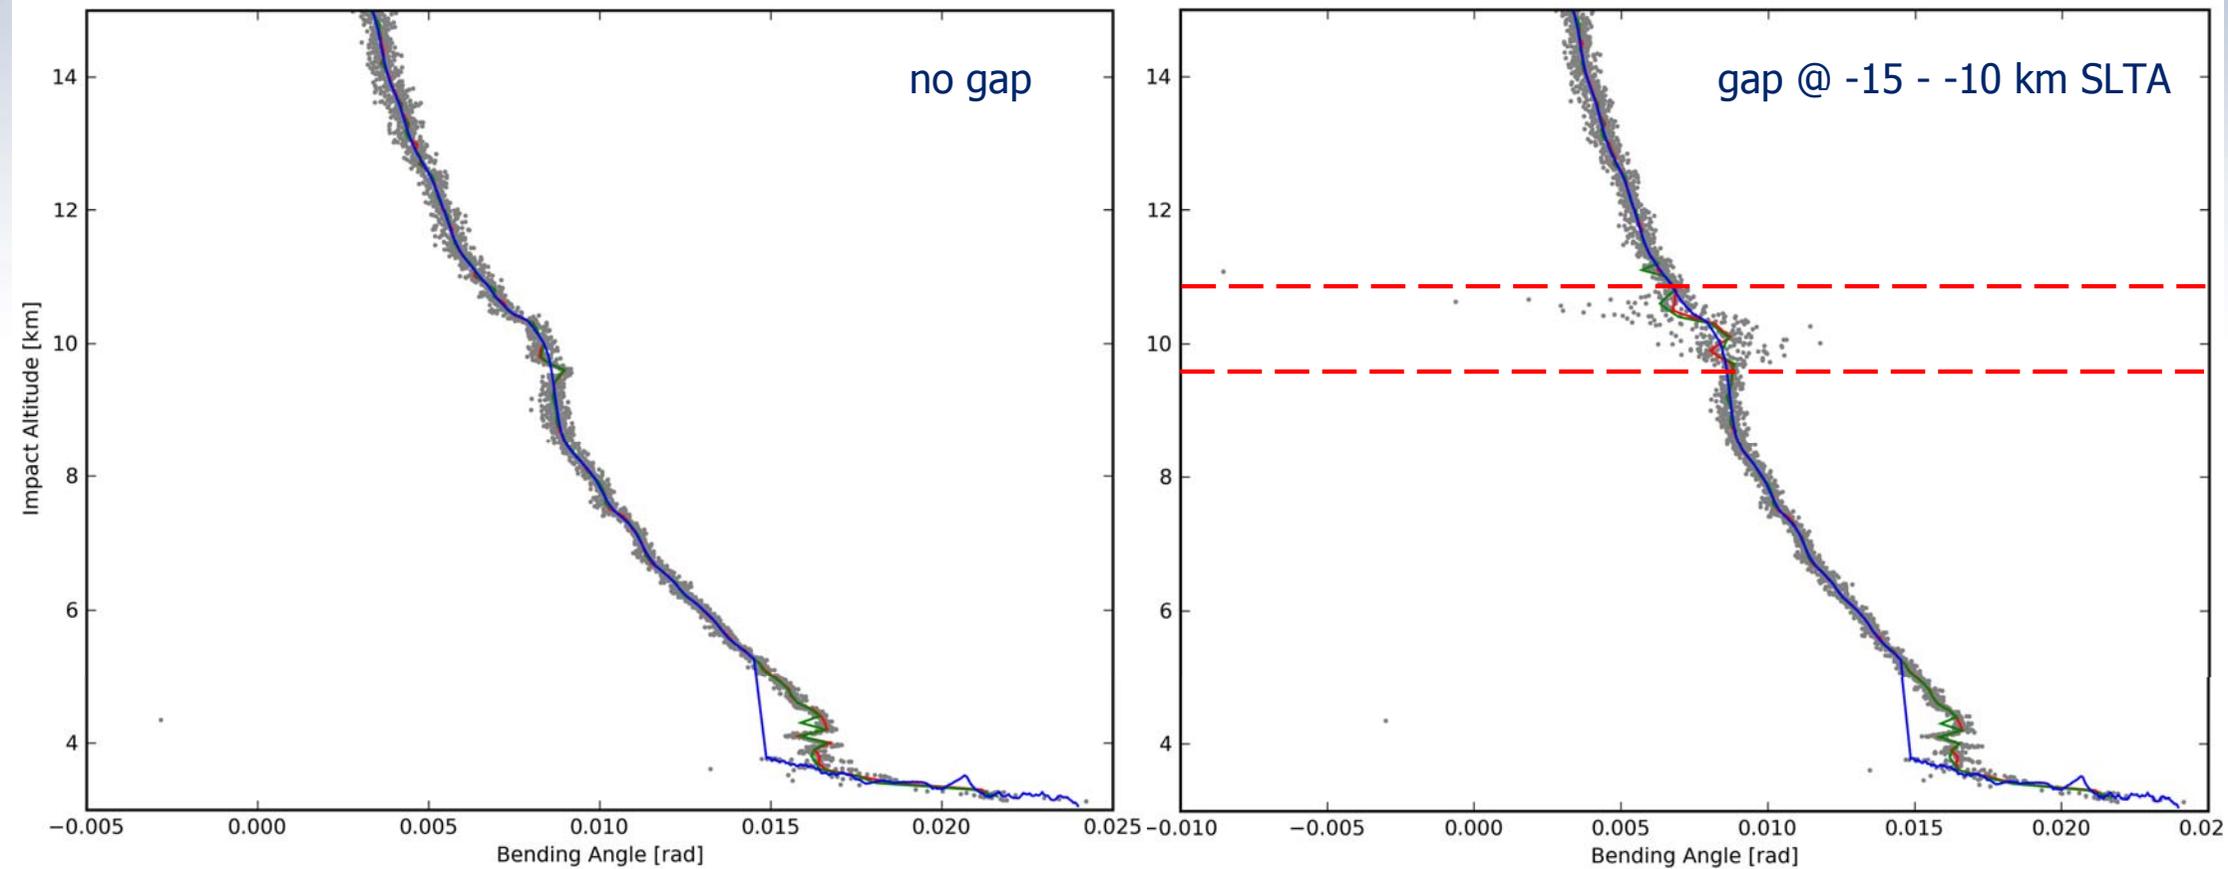

Gaps in rising occultations

If the receiver doesn't have a measurement...

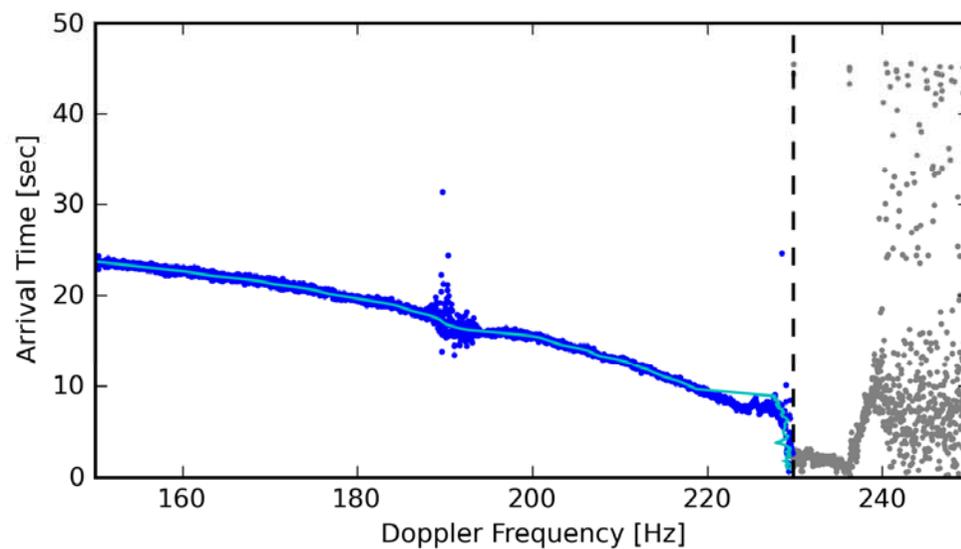

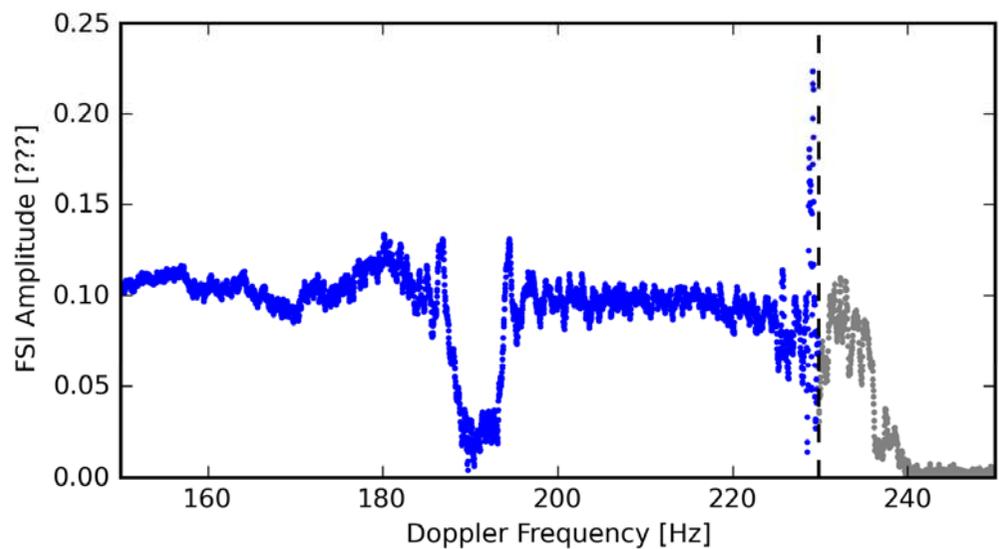

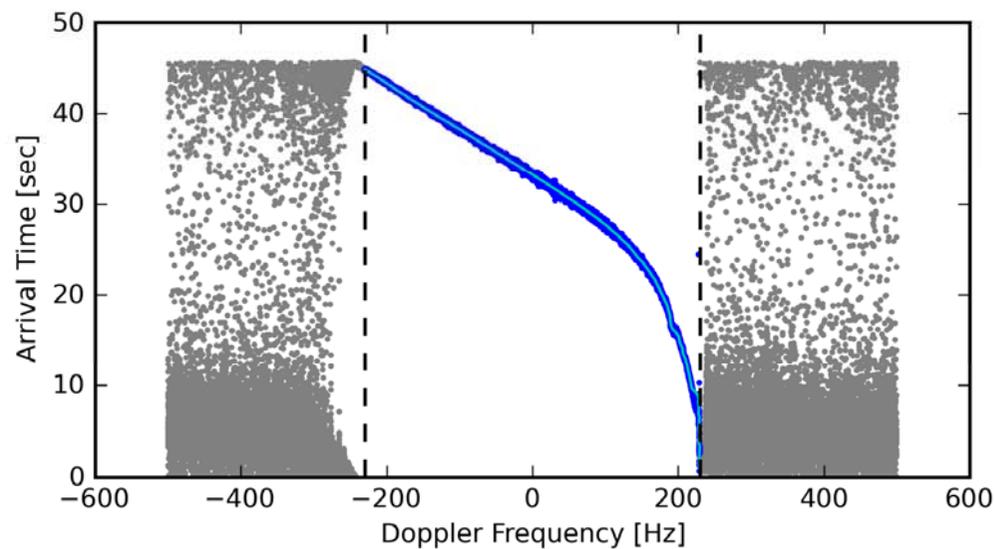

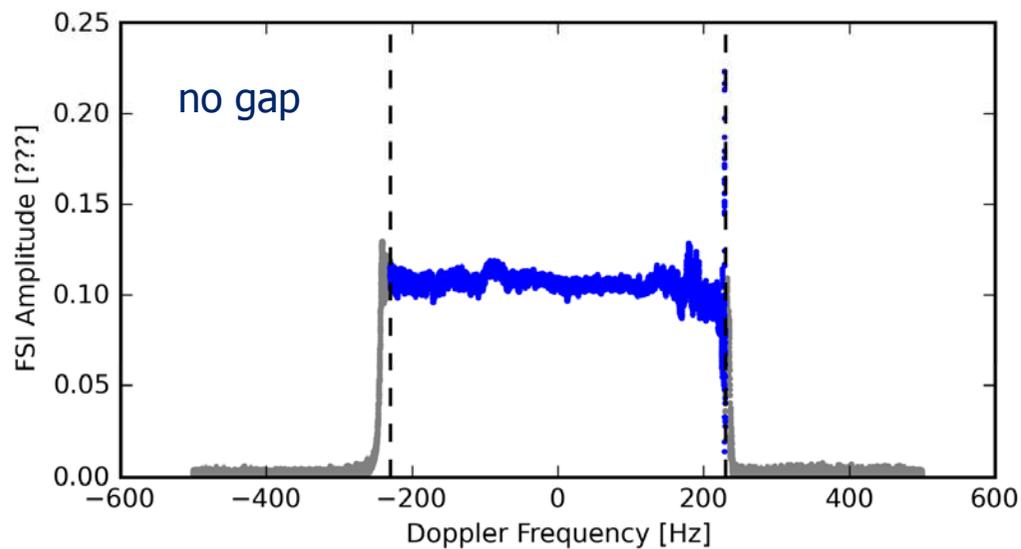

- ...we fill the "measured" complex signal with zero...
- ...do the usual FSI...
- ...and remove / flag the "interpolated" data as missing.
 - assumes that data gaps affect retrievals locally (and can be identified in impact parameter / bending angle space)
- Alternatively process data segments individually (as we do in our GO retrieval)
- We want to avoid interpolating over gaps – if the receiver didn't measure anything, we don't want to pretend otherwise
- Caveats:
 - Refractivity users will have to do their own interpolation over gaps
 - We haven't yet done a robust implementation of this

Simulation

- gaps are mapped into localized regions with increased uncertainty in arrival times / bending angles
- other parts of the profile do not seem to be affected

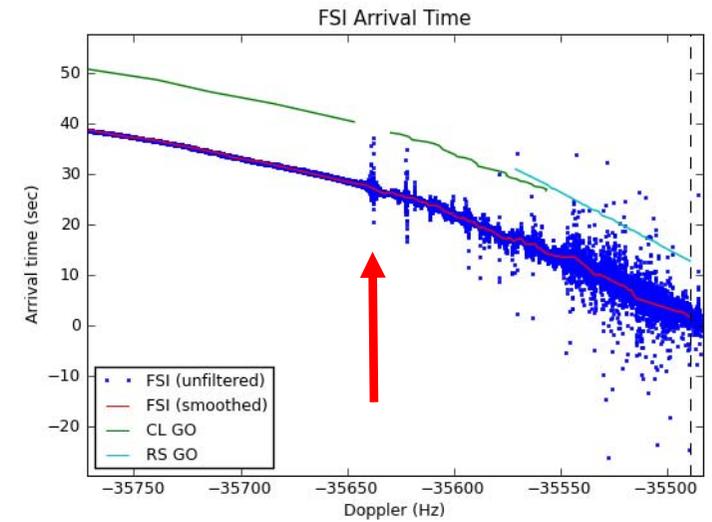

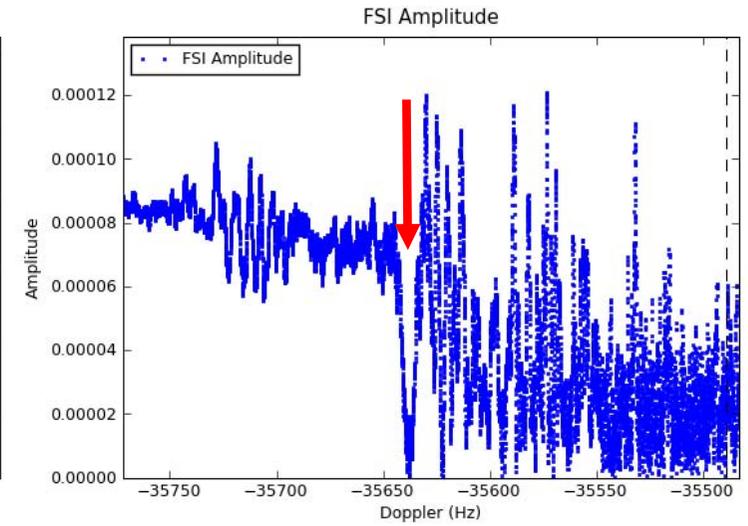

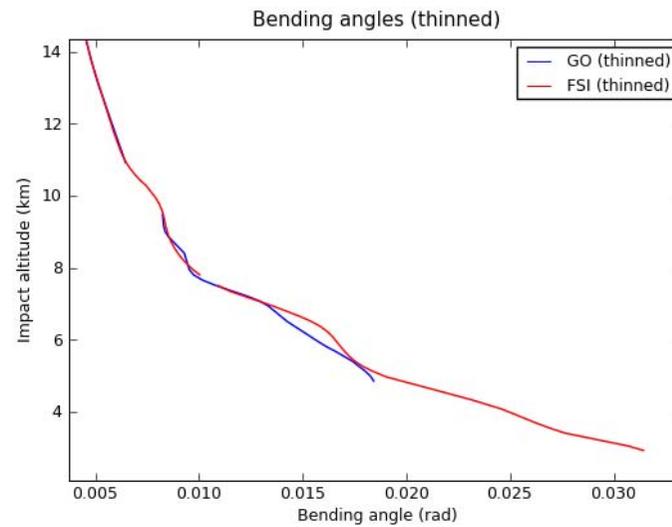

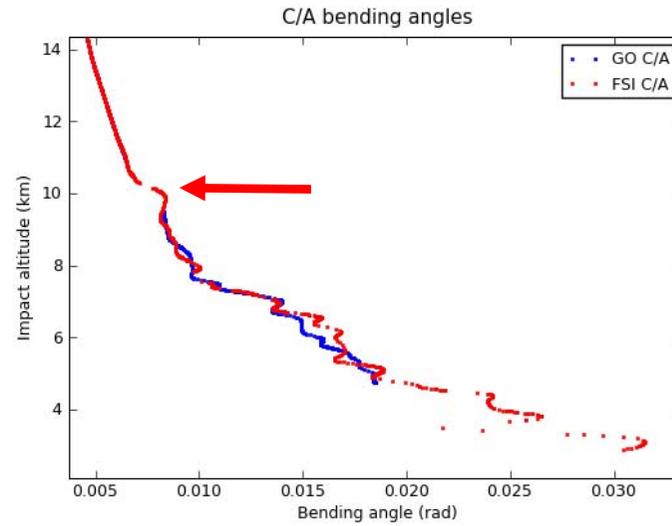

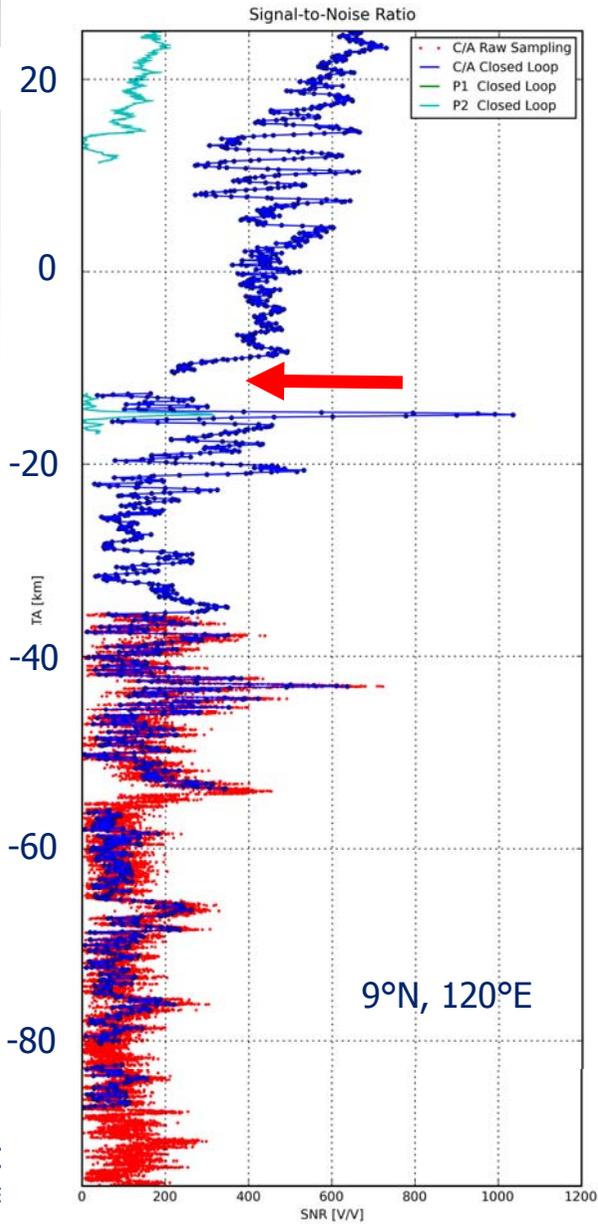

Simulation (cont'd)

Real Example

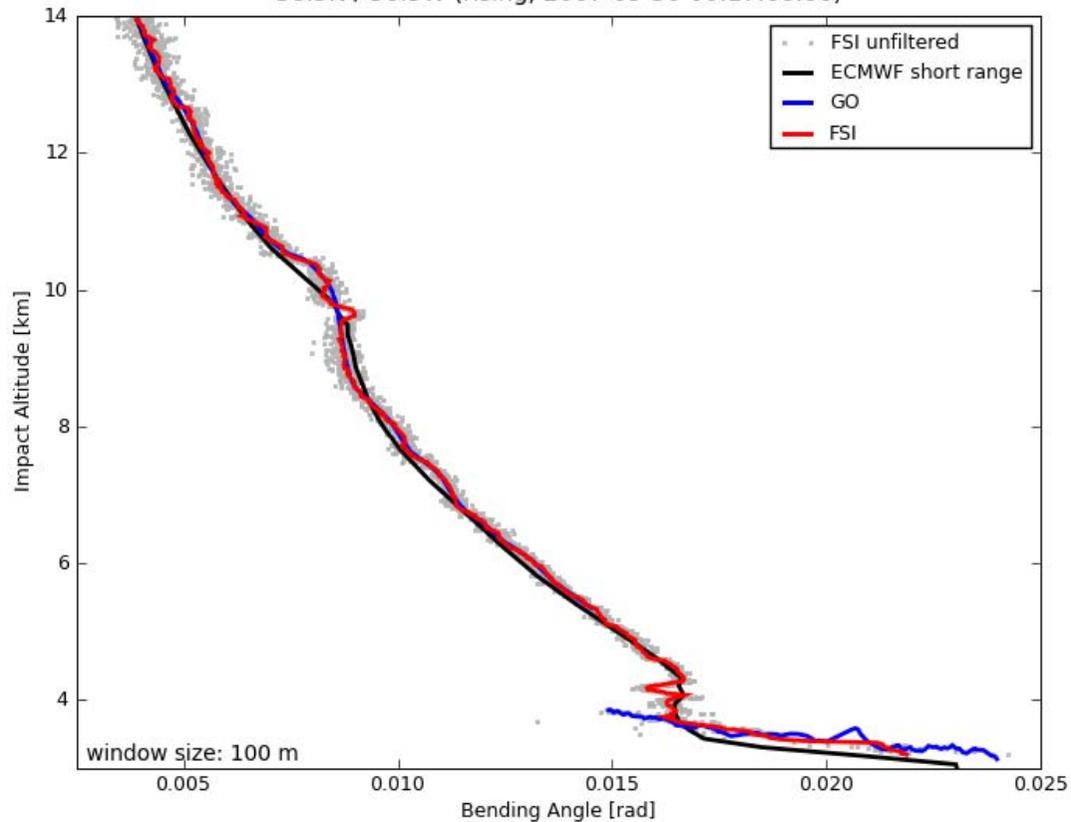

SLTA [km]

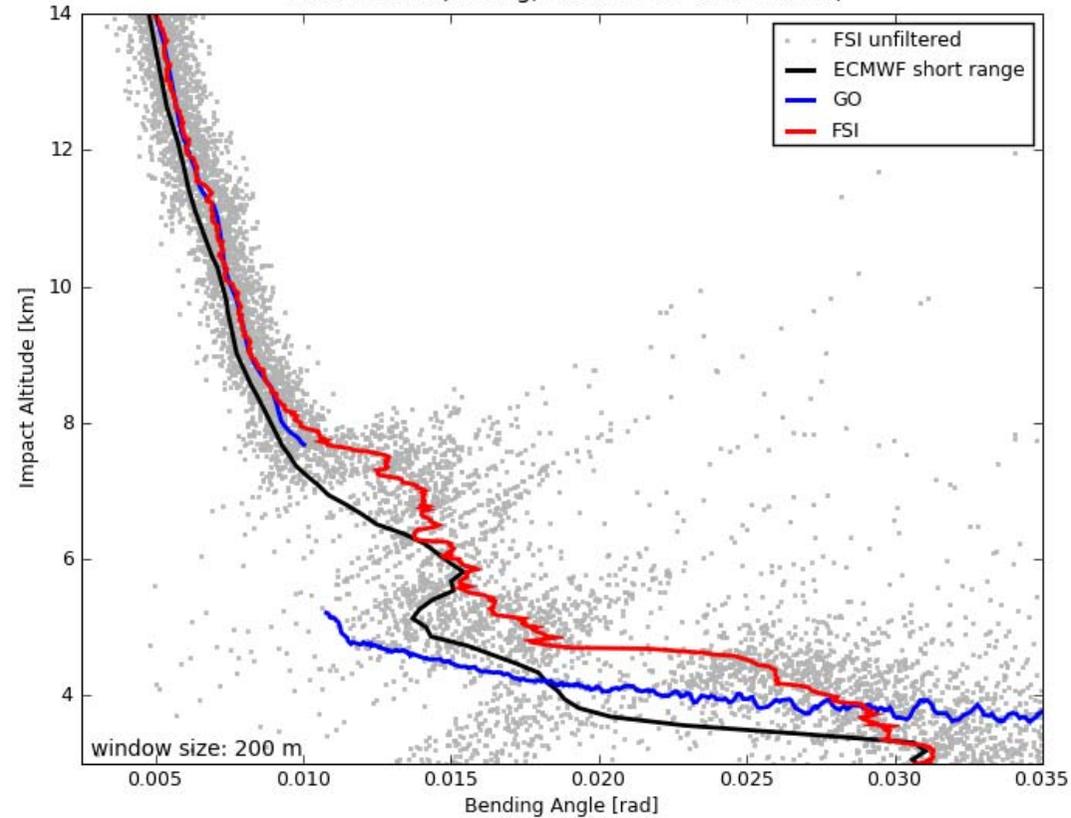

Bending Angle Example – High Latitudes

58.5N / 58.5W (rising, 2007-09-30 00:17:08.66)

4.6S / 25.2W (setting, 2007-09-30 00:12:57.87)

Summary: GRAS Issues

- Gaps in RS data due to loss of C/A code tracking (expected by GRAS design)
- Gaps in CL data not covered by RS in rising occultations (33% of rising / 16% of all occultations)
 - will rise uppermost RS SLTA as mitigation (October?)
 - firmware changes under discussion
- low P1/P2 SNR (7% of all occultations)
 - retrieval “noisier” (more like CHAMP) than the average GRAS occultation,
 - some are completely useless
- occasional amplitude saturation events in RS under moderately high SNR conditions
 - probably not much of an issue, especially if RS data is downsampled to 50Hz

Summary: Studies

- European study to investigate GRAS RS data characteristics comes to an end
 - CL data / stratospheric (geometrical optics) retrievals
 - generally in good agreement, in particular w.r.t biases ($< 0.1\%$ between centres from 10 - 30 km)
 - differences in sdev mostly understood in terms of filtering as far as GO algorithms are concerned (there might also be the one or other bug at EUM ☹...)
 - RS data / tropospheric retrievals
 - all centres have capability to process GRAS raw sampling data with advanced retrieval algorithms (all independent)
 - structural uncertainty issues below 10 km in the troposphere, especially if data is affected by multipath
- Structural uncertainty study (UCAR) focusing on GO processing of GRAS data nearly complete completion
 - GRAS low level processing implemented at UCAR
 - stratospheric GO retrievals show good agreement between 10 and 30 km, also with independent level 0 data reconstruction and POD
 - strong quality control at UCAR, removing about 15% of occultations
 - extension focussing on tropospheric data (w/ DMI) beginning soon

Outlook / Ideas

GRAS Operations:

- Metop A will continued to be operated in parallel to Metop B...
- ...doubling the number of occultations from GRAS instruments in mid 2012

Raw Sampling:

- Based on study results, we re-engineer the operational processing software for GRAS to include tropospheric processing
- Planned to become operation mid-2011 (early parallel data stream for testing available in October 2010)

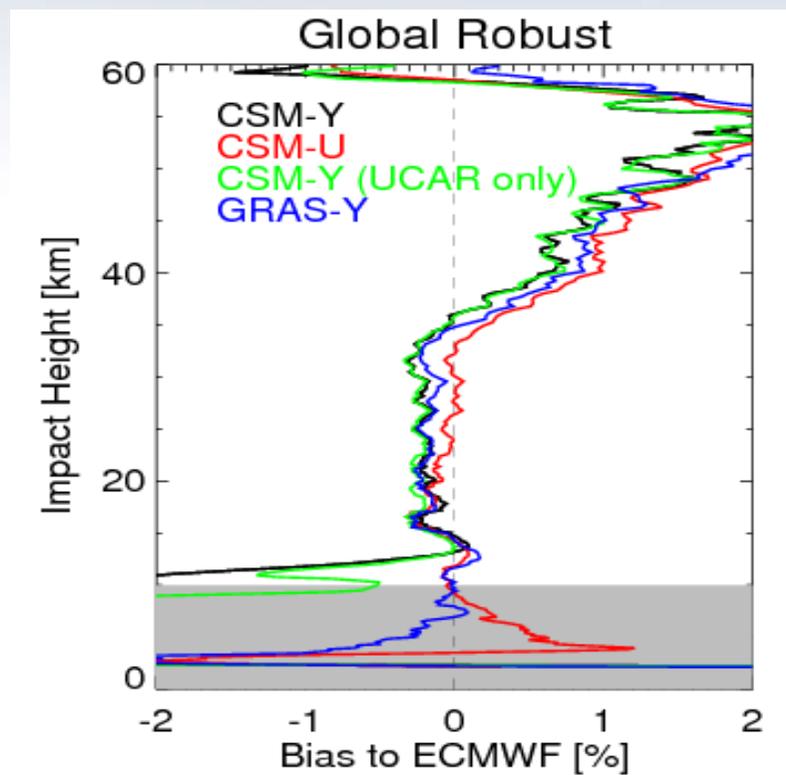

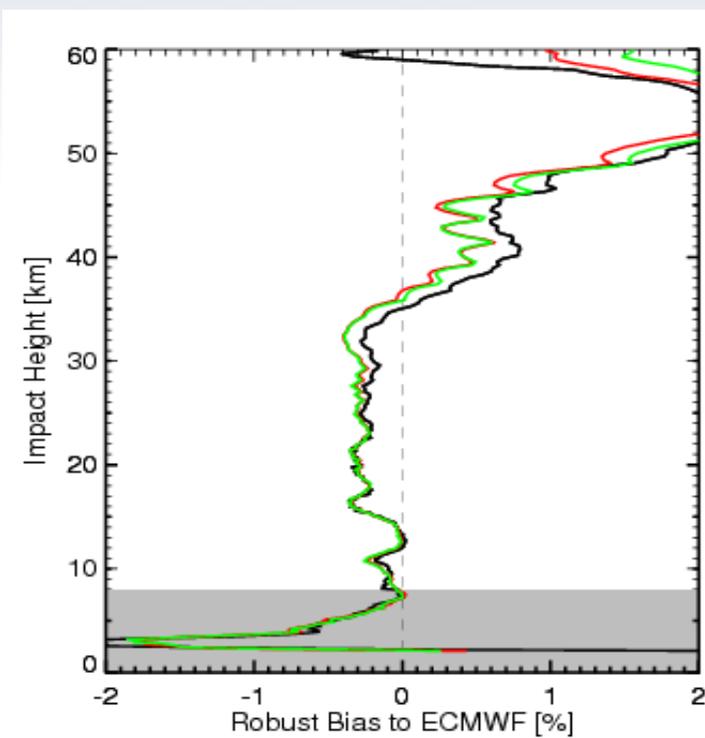

Overall:

- need to work on structural uncertainty issues in tropospheric retrievals
- we do not yet fully exploit GRAS specific data characteristics – nearly everyone just downsampled the 1 kHz RS data to 50 Hz to make it look like COSMIC...
- need to implement mitigations for receiver issues, in particular data gaps in rising occultations

Thank you.
